At least one process employs a principle in distillation that is unique, and is known as 'digestion'. The Ryan retort is partly filled with a heated hydrocarbon liquid of high density. This may be an oil, melted paraffine, or any other hydrocarbon with a relatively high temperature of vaporization. Into this liquid is charged pulverized shale, and the charge is constantly stirred. Heat reaches the shale through the bath of oil, the nascent oils thus generated dissolving or blending in the bath. The temperature maintained during the digestion is relatively low and this stage of the process is complete when the shale has become a muddy sludge. During digestion there is evaporation, from the surface of the bath, of the lighter volatiles, such as gasolene and naphtha, which are recovered at the condenser. The retort continuously discharges its sludge into a tall tank filled with gasolene or naphtha, which absorbs the oils while the earthy material is settling to the bottom. The wash-tank is steadily supplied with fresh light oil while the overflow goes to the refinery for fractionation.

It is claimed that this process will educe more than twice as much oil as does dry distillation, because no fixed gas is generated.

FUELS FOR RETORTING. Heat for the retorts will be secured by burning crude shale, spent shale, and the fixed gases. In this way the oil-shale distillation plant will require no fuel from outside sources. Raw shale, just as mined and crushed, may be used with complete success on any ordinary type of grate, but, owing to the high content of ash remaining from the burning of shale, the stoking of fires by hand offers objection. Automatic stokers and chain-grates will be used to obviate this difficulty.

After the removal of all volatile hydrocarbons from the shale, the residue, or spent shale, carries a considerable amount of fixed carbon or coke, which, as in French practice, can be advantageously used as fuel in the furnace, preferably discharging it, while hot, directly from the retort onto the grate. In most types of retort it is improbable that this fixed carbon will furnish sufficient fuel, so it is planned to burn the fixed gases, from the retort, as additional fuel. It is roughly estimated that the usual dry distillation of oil-shale of the one-barrel grade will produce 2000 cu. ft. of this gas, a rich hydrocarbon that burns freely. Sufficient experience has not as yet been gained to arrive at close estimates regarding the fuel consumption, but it is generally held that retorts will supply the requisite fuel in the two waste products, spent shale and fixed gas, possibly augmented by raw shale.

The condensation of vapors from retorts is accomplished by the ordinary air-cooling of pipes. Water-cooling often causes a congestion of the pipes by the rapid condensation of the heavy fractions.

REFINING OF SHALE-OIL will be as essential as refining of well-oil, that is, if the same uses are made of the products. There will be no special differences between procedures in the two cases. In general, the same marketable liquids will be recovered.

There are as great differences between the oils from different shales as there are between the petroleums from different oilfields. Most shale-oils are relatively lower in gasolene content, unless cracking is practised. Usually the content in lamp-oil or kerosene is sufficiently high to warrant the introduction of cracking. Shale-oils, as a rule, yield splendid grades of lubricating oils and greases.

A refinery will be more or less indispensable in every oil-shale plant. The use of fractionating retorts is recommended by their inventors upon the ground that at least some of the initial fractions will be immediately ready for market or, at any rate, they will be of such grades that they can be sold to custom refiners at much better prices than can be had for the total oil.

All shale-oils and their fractions are either dark in color at first or they take on continually darker tints as they age. This discoloration is probably due to traces of sulphur, although some persons believe it is caused by a natural dye. Shale-oil gasolene may be colorless as it comes from the still but it will be red the following day. To seal it from the atmosphere makes no difference. It appears that coloration may be hastened by sunlight. An automobile was driven several days with shale-gasolene as fuel and no deposit was left in the cylinders.

Products and By-Products. I have already stated that I believe early operations in oil-shale could well be restricted to the manufacture of a few staple liquids. The production of simple fractions from the total oil will prove profitable. Such products would include naphtha and gasolene as one product for motor-fuel; kerosene, an engine-fuel, or crackable into motor spirit; light and heavy lubricating oils; soft and hard greases; and a residuum heavy in paraffine or asphalt, or both, this last product varying with the character of the shale treated.

The average fractionation of shale-oils, as estimated from many tests, is: naphtha and gasolene, up to 150°C., 9%; kerosene, to 300°C., 37%; light lubricating oil, to 335°C., 20%; heavy lubricating oil, to 354°C., 23%. The average residuum from distilling shale-oil to 300°C. is a good agent for the flotation of minerals and one or two companies propose the standardization of blends to satisfy the requirements of flotation-oil consumers. With certain flotation machines and with certain minerals, the best results have been obtained with residuums at different temperatures of distillation, this simply meaning more or less of the lighter fractions in the blend. It is thought by some that approximately 50% of the total oil yield from shales could be standardized into products of this nature, saleable at around 50c. per gallon.

Potash exists in small amount in most oil-shales. It is claimed that the heat to which the shale is subjected during distillation converts the available potassium salts into readily soluble conditions. Attention may be given later to the commercial recovery of potash.

Some beds of oil-shale, such as those in Beaverhead county, Montana, are found to contain phosphoric acid. Samples taken and tested by C. F. Bowen of the U. S. Geological Survey show that the equivalent content in calcium phosphate varies from 5.7% to 33.96%. The phosphate is extractable from the spent shale.

Nitrogen occurs in all these shales and many operators anticipate the recovery of it in the form of ammonium sulphate. Dean Winchester, in Bulletin 691-B, U. S. Geological Survey, states that the average of 18 samples of the Green River oil-shale showed an average nitrogen content of 0.64% equivalent to 59.4 lb. of ammonium sulphate per ton. In commercial practice it will not prove economical to recover all the nitrogen. The manufacture of fertilizer will probably be one of the first by-product steps in the shale-oil industry.

A recent suggestion concerns the feasibility of manufacturing lamp-black from the heavy residue after removal of oils. It is believed that this residue might be burned directly and produce approximately 25% of its weight in commercial grades of lamp-black. If the residue be first rendered gaseous by additional apparatus and the gas then burned, approximately the same amount of soot may be made and this will be of a grade known in the trade as 'carbon black', which commands a higher price. In view of the increasing consumption of these substances in several trades, together with legislative prohibition in most States covering the manufacture of them from natural gases, it would seem that this proposal has merit.

There has been much talk about the manufacture of dyes from the heavy residue from shale-oil but it does not appear that this work offers particular attraction in the near future. It is improbable that any dyes not already being made from coal-tar would be discovered, and the research involved in working out methods would be extensive.

Status of the Industry. I am daily asked regarding the status of this oil-shale industry. There are many angles to the question and too many points to be discussed, so I shall not go into more than a few at this time. I have endeavored to show why progress has thus far been slow apparently. The progress to date has been largely along lines somewhat intangible to the public. I maintain that it has been appreciable, and that it portends big things commercially in the future. Processes have been developed to stages that satisfy prospective operators; I expect a few companies to erect relatively small plants this season and to be producing oil before next winter.

Interest in the industry is wide-spread. Projects are afoot in New Brunswick, Kentucky, Missouri, Colorado, Utah, Wyoming, Montana, Nevada, New Mexico, California, and Alberta. One hears most about the Utah-Colorado field because it is the largest and has been given most publicity in Federal publications. Equally good oil-shales are found in the other regions and in quantities warranting companies in starting commercial activities. The natural resources exist beyond doubt and efficient processes are becoming available. It is not supposed that perfection has been attained by any inventor, but I believe the time has arrived when projects may be started legitimately. As the handling of shale proceeds upon a large scale, operators will discover ways of improving efficiency, of lowering cost, and of increasing capacity. I have purposely avoided any discussion thus far of figures for costs of plants and for costs of operation, as likewise figures for values of products and for profits. Estimates in these directions vary tremendously in the opinions of different persons. They will vary with the process selected and with the scale of operations; however, I venture the remark that the public has been given exaggerated figures covering all of these points, especially with regard to the amount of capital that will be involved in erecting plants. I maintain that the expenditures required to establish and maintain oil-shale plants are no higher than those involved in other industrial projects of similar magnitude. When I run across persons who 'knock' this industry, I always find that they have been misinformed and that they base their criticisms upon unsound premises. I insist that success in this industry will be attained only when reliance is placed upon technical guidance. The treatment of oil-shale is a practical application of organic chemistry. Supervision of such work should not be assigned to men who lack qualification in this line nor to those who are deficient in plant-operating experience. The selection of a process should not be left to promoters. Stockholders in oil-shale companies would do well to insist that the first official appointed be a competent technologist, a man who knows enough about engineering and chemistry to take charge of all matters connected with the acquisition of land, the selection and erection of machinery, and the control of every phase of the operations.

Dredging Results of Canadian-Klondyke Company

The report of the receiver and manager, H. G. Blankman, for the Canadian Klondyke Mining Co.'s properties, near Dawson, shows that the operating profit in 1918 amounted to $216,963. This was reduced to $44,571 by extraordinary charges. The gold recovered by the dredges and sundry operations was $481,423. A comparison of gravel dug and costs is summarized below:

	1916			1917			1918		
Dredge	Yards	Yield, cents	Cost, cents	Yards	Yield, cents	Cost, cents	Yards	Yield, cents	Cost, cents
1	849,735	43.48	19.26	611,160	29.50	19.99	278,965	22.65	19.70
2	2,240,350	11.53	6.29	2,188,575	10.66	6.10	1,407,750	11.59	6.24
3	1,732,065	6.19	4.83	1,476,430	9.87	5.87	....	....	....
4	1,128,250	10.85	8.68	1,352,185	19.20	8.97	2,368,695	11.72	5.15
Last Chance...	143,060	20.06	15.66	20,000	7.45	5.22	245,500	11.72	2.16
Total	6,093,460	14.21	8.35	5,649,350	14.76	8.51	4,300,910	11.19	6.28

Upon adding administration, engineering, power, bond interest, and other extraordinary charges, the costs were increased to 14.22, 14.46, and 10.28 cents per yard, respectively. Thawing for No. 1 boat in 1918 cost $26,306, for No. 2, $6687, and for No. 4, $6497. The receiver places the total current assets of the company at $506,901, and current liabilities $30,569.

Sales of electric power by the Pacific Gas & Electric Co. to consumers in California last year totaled $12,384,499. Of this the mining industry paid $851,466, equal to nearly 7%. The output of electric energy was 922,037,604 kw-hr., so mining used 64,540,000 kw-hours.

Leaching Copper Ore in Utah

The leaching plant of the Utah Copper Co. during 1918 treated 431,113 tons of oxidized ore, an average of 1190 tons per day. The usual difficulties in starting a new plant were encountered. Shortage of labor and acid were also responsible for the small tonnage. Operations in the crushing and leaching departments were entirely satisfactory, but the capacity of the scrap-iron launders was insufficient, and cold weather interfered with precipitation during the winter. Basic iron phosphate, precipitated with the copper, rendered the drying of the product slow and difficult. Methods for handling the precipitate have been devised, and in future the plant should have a normal economical capacity of 3000 tons daily.

The ore averaged 0.822% copper, of which 0.665%, or 13.30 lb. per ton, was in soluble form. The recovery in leaching was 11.10 lb. per ton, corresponding to an extraction of 83.31% of the soluble copper. The recovery of the metal from the solution, in the form of a precipitate, was 0.5297%, or 10.594 lb. of copper per ton. The precipitate averaged 48.7727% copper, 9.6066% iron, and 2.74% insoluble. The consumption of 60°B. sulphuric acid averaged 55.7 lb. per ton, corresponding to 5 lb. of acid per pound of copper recovered in leaching.

The cost of milling, leaching, precipitating, handling tailing, and general expense at the leaching plant averaged $1.0568 per ton. This large figure is due principally to the higher cost of labor and supplies, but also to decreased efficiency and to the comparatively small quantity of ore treated.

The average cost per pound of net copper produced from the precipitate was 16.85 cents. In addition to the copper precipitated, there remained in solution 670,000 lb., of which 627,000 lb. is recoverable. Taking this into consideration, and allowing for the additional expense to cover precipitating, smelting, refining, and marketing of the 627,000 lb. of copper, the cost per net pound of all copper from leaching plant will average 15.089 cents. Operation of this plant was discontinued on December 31, 1918, on account of curtailment of production.

Iron compounds in asbestos detract from its value for electrical insulation, and recently experiments have been made for the removal of such compounds. It has been found that treatment with a 2% aqueous solution of oxalic acid for 48 hours, followed by washing with water, increases the electrical resistance of such impure asbestos, while at the same time the strength of the asbestos is not affected. The second method is to heat the asbestos for 20 to 24 hours in a current of hydrogen or carbon monoxide at 390 to 400°C., followed by washing with very dilute hydrochloric or sulphuric acid, and afterward with water. In March, 9291 tons of asbestos was imported from Canada, worth $26 per ton.—O. Bowles in April report of U. S. Bureau of Mines.

Minerals Separation v. Butte & Superior

Hearing of the Case Before the U. S. Supreme Court. Arguments for the Petitioners, Minerals Separation, Ltd.

ARGUMENT OF HENRY D. WILLIAMS

MR. WILLIAMS: The patent here in suit was before this Court in the case of Minerals Separation, Limited, v. Hyde. There the issue concerned the validity of the patent, as infringement was too clear to require argument if the patent were valid. In the instant case the issue is infringement, since validity is conceded.

As your Honors may recall, the defendant Hyde in that suit installed this air-froth flotation ore-concentration process for the Butte & Superior Mining Co., the defendant here. The defendant's participation in and continuation of that infringement are now before this Court.

In the Hyde case the District Court of Montana found that the patentees had discovered a new process, with a new result, and it was therefore patentable. The Circuit Court of Appeals of the Ninth Circuit reversed that finding and held that the process and the result were old, and that the only new thing which the patentees had discovered was that such an old process and old result could be achieved with a smaller amount of oil (which is one of the materials used in the process) and a smaller amount of oil than was used in any of the prior processes. That decision was reversed by this Court on *certiorari*, and this Court found, in agreement with the District Court, that the process and result were new and the invention was patentable.

The decision of this Court in the Hyde case was rendered on the 11th of December 1916. The defendant almost immediately began experimenting in its mill with a view to finding a way which, in its judgment, would enable it to avail itself of the benefits of the patented process and yet avoid the decision of this Court.

For two years prior to that time the defendant had used pine-oil as the only oil used, in a procedure which it admits infringed the patent. The defendant endeavored to avoid the continuance of the use of this pine-oil, and tried some 16 different mixtures of oils, without other alteration or procedure, but was unable to satisfactorily produce the result desired without continuing the use of the pine-oil which had formerly done the work, and had to content itself, finally, with adding to the pine-oil, which continued to do the work, kerosene oil and fuel-oil, or equivalents, which did not do the work. The use of such a mixture was continued from about the 7th of January, 1917, down to the time of the trial of this case in April, 1917. Prior to January 7, 1917, the defendant used a pound and a half of pine-oil to the ton of ore—7/100 of 1% on the ore. After January 7, 1917, and because it was using the kerosene and the fuel-oil above referred to in admixture with the pine-oil, defendant had to slightly increase the amount of pine-oil to overcome the deleterious effects of the make-weight oils which it added, but the increase did not average as much as one-tenth of 1%.

THE CHIEF JUSTICE: Do you mean eight-tenths were added?

MR. WILLIAMS: They added eight-tenths of these oils, which did not do the work of the process. The defendant, in his altered procedure, had to use as much as two-tenths of 1% of pine-oil instead of a little less than one-tenth of 1%, and added to that eight-tenths and a little bit more—just enough to go over 1%—of these oils that did not do the work.

MR. JUSTICE CLARK: I understood you to say that under the modified practice it was still less than one-tenth of 1% of pine-oil?

MR. WILLIAMS: Still less than two-tenths of 1% of the pine-oil.

All of those procedures were held by the District Court, after a five weeks' trial in open court, to be infringements of the patent in suit. The Circuit Court of Appeals, upon an appeal by the defendant, held that none of these procedures with more than one-half of 1% of total oils so used were infringements. The theory of the defendant and of the Circuit Court of Appeals was that this Court, in the Hyde case, construed the patent in such a way as to limit the language of each claim, whatever its natural meaning would otherwise be, to one-half of 1% of oil, and of any oil, whether it did the work of the process or not.

There are, therefore, two questions before this Court.

THE CHIEF JUSTICE: Did the Circuit Court of Appeals hold that they could add any percentage so as to make up the amount, although that added percentage was not a factor in what was done at all?

MR. WILLIAMS: That is what the Circuit Court of Appeals held, and, further than that, they put the limit at one-half of 1%.

THE CHIEF JUSTICE: I know that, but I was just thinking instead of adding, they didn't add anything. As a matter of fact they didn't add anything; they added nothing.

MR. WILLIAMS: That is our viewpoint.

The two points, as I have indicated them, are

FIRST: Shall the claims of this patent be read and construed in the light of the language used in the claims in the natural meaning of such language, or shall these claims, whatever their language, be so read as only to include, so far as oil is concerned, one-half of 1% as the maximum limit?

SECOND: In this process is the oil referred to in the claim an oil which will produce the mineral-air-froth concentrate which is the object of the process, or shall all oils be counted as the oils of the process, whether or not they function in the process?

As to the first question, the Circuit Court of Appeals and the defendant here attribute to this Court the finding in the Hyde case that a mere matter of degree is patentable. Their viewpoint is that this Court agreed with the Circuit Court of Appeals in finding the process of the patent in suit had no new feature in it whatsoever except the novelty incident to the use of less oil, to operate in the same manner, to perform the same functions, and to produce the same result as the prior art processes.

Having attributed this remarkable finding to this Court, they next argue that since it appeared in the Hyde case that in practical operations it had not been found necessary to use more than two-tenths of 1% of oleic acid (which is the oily liquid described in the patent—of the example of the patent) or other equivalent oil to work the process and obtain the results called for, therefore they are free and everyone is free, if they choose to be uneconomical, to use more than one-half of 1% of oil and thereby to escape infringement.

Mr. Justice McReynolds: What sort of oil is this you say they use?

Mr. Williams: Pine-oil.

Mr. Justice McReynolds: Suppose they use more than 1% of that?

Mr. Williams: The evidence is that they could not get the result.

Mr. Justice McReynolds: It was definitely stated here before that if they used more than 1% of oil you had no objection.

Mr. Williams: No, your Honor.

Mr. Justice McReynolds: Yes. I asked that very particularly. My memory is very distinct. I understood you to say that until you reduced it to less than 1% you had no claim whatsoever.

Mr. Williams: Yes, but that was an operation under certain specific conditions with oleic acid and Broken Hill ore, and in that operation without any question the invention did not appear until you got down, in reducing the amount of oil, to one-half of 1%, and that operation cannot be carried on under those conditions and produce the process with more than one-half of 1%, and the defendant has demonstrated that in this case, because the defendant, in its mill, used this oleic acid for some two years, and the defendant did not use it well, and at one time he got up to a little more than nine pounds of oleic acid to the ton of ore (and ten pounds is one-half of 1%) and that is the greatest amount of oleic acid that has ever been used in concentrating ores by this process, and it is the greatest amount of any bubble-modifying oil mineral-froth-forming oil that has ever been used in this process, and the fact is now as it was then; but your Honors will remember in the other case there were certain prior art patents. The defendant carried on certain experiments. One of them—the one that was most important, we will say—used 3.6% of an oil, cotton-seed oil, which was a bubble-modifying mineral-froth-forming oil. We said: That is legerdemain of the laboratory. We proved that it could not be used in practical operations. That stands uncontradicted. We were not asked to say whether or not, if with that oil you could carry on the process, it would be within the patent. We were not asked that. But our witness in that case, Dr. Liebmann, when faced with that on the witness stand, said: If you can carry on this operation with 3.6% of cotton-seed oil, then it is the process of this patent. That was the evidence in the Hyde case, and that stands uncontradicted in this case.

Mr. Justice Day: What do you claim now is the particular merit of your invention recognized by this Court in the former case?

Mr. Williams: This Court recognized the merit of the invention as bringing about a new function of oil, a new operation, a new function of air, and a new froth concentrate, something that had never been produced before.

Mr. Justice Day: Oil in any quantity?

Mr. Williams: The element of oil quantity was an incident of the birth of the invention, and it appears to be an incident of the use of the invention. This Court did not express any opinion on the subject of oil quantity. This Court described the incidents of the birth of the invention, and this Court took into consideration—I was to take it up a little later in my argument on another matter.

Mr. Justice Day: I beg your pardon. Pursue your own course.

Mr. Williams: Four times in the decision of this Court the new froth-concentrate is described, and it is made quite clear that the prior art used oil-lift, and that the process in suit used chiefly air-lift; that it developed a new function of oil in combination with air bubbles producing a mineral-froth, in carrying on a process of concentrating ores.

The Chief Justice: I understood you to say, in answer to my question, and you say now, that the process of this patent could not be carried on with more than two-tenths of 1% of oil; is that it?

Mr. Williams: If the oil is an oil of that character which upon agitation produces a froth—

The Chief Justice: Your proposition now is that if the oil used is the character of oil you describe, what is called pine-oil, the process could not be accomplished if more than two-tenths of 1% is used, therefore the patent is limited to two-tenths of 1% of the character of oil that you describe. That is your proposition now, as I understand it.

Mr. Garrison: No.

Mr. Williams: I don't think that we ought to be bound by——

The Chief Justice: If you did not say that, all right, but I thought you had been saying it. I asked you what you have been saying. I want to know what you said. I only want to understand you right.

Mr. Williams: It is the fact——

The Chief Justice: You say that?

Mr. Williams: Yes; it is the fact.

The Chief Justice: Now, then, what do you complain of? That they allowed something to be added, and set your patent aside? Because to allow oils to be added that did not produce the result adds nothing and looks like a fraud, if I may use a plain word——

Mr. Williams: That is right, your Honor.

The Chief Justice: A mere scheme to beat your patent, because if they added something which did nothing, they added nothing, and they went on using their old process.

Mr. Williams: Continued as they had before.

The Chief Justice: So your claim, as you now state it—and I want to follow it, if I can—your claim, as you now state it, is that the Court really treated your patent as referring to any oil, and allowing people to add any oil would thereby frustrate your patent?

Mr. Williams: Yes, your Honor.

Mr. Justice Pitney: Did you in your answer use the term "old process"?

Mr. Williams: I may have.

Mr. Justice Pitney: How old is it?

Mr. Williams: If I said: "old process" I meant they continued to do what they had done before the decision of this Court. If I used the words "old process", I used them inadvisedly.

Mr. Justice Pitney: What you say is that they are using an inefficacious, non-active oil, which does not contribute to the process at all?

Mr. Williams: Yes; and not under any conditions are they going back to those things that were described in the written documents, in what we refer to as the prior art, or approaching anywhere near it.

Now in adding this fuel-oil and kerosene they did just one thing: they impaired the results of the process. Pouring in this material which did nothing to help the process, they injured it, and therefore they suffered a diminution of profit, and as a matter of fact they lost one-eighth of the profit which they would have otherwise made from their infringement by reason of the fact that they poured in these oils.

Mr. Justice Brandeis: That is, they retarded and obstructed the process?

Mr. Williams: Yes; a mere obstruction.

The Chief Justice: More load to carry.

Mr. Williams: They had to increase the pine-oil. And, more than that, they suffered a loss. Briefly, a million dollars a year was the loss. The profit for the year 1916, when they used the process at its best advantage, was $8,500,000; so they got down to $7,500,000 profit. That was the rate in this year in which they added these oils and injured the process. But certainly you cannot avoid a patent by using the process somewhat badly.

Now in the Hyde suit there was no occasion to consider any other oil than the identical example of the specification, oleic acid, a fatty acid—not an oil, but an oily liquid having the physical characteristics of an oil. The defendant used it, and the defendant used it at less than two-tenths of 1% on the ore. But in the Hyde decision this Court was called upon to pass upon the sufficiency of that disclosure of the specification which gave directions for discrimination as between oils and as to the quantity of oil to be used in any case in dealing with the infinite variety of ores with which the process was to be used. That part of the specification I will just take the time to read. It will be found at page 1, lines 61 to 69.

"The proportion of mineral which floats in the form of froth varies considerably with different ores and with different oily substances, and before utilizing the facts above mentioned"——

And that is the disclosure of the discovery of the invention.

"—and before utilizing the facts above mentioned in the concentration of any particular ore"——

Mr. Justice Holmes: What are you reading from?

Mr. Williams: Page 1 of the specification, lines 61 to 69, second column.

Mr. Justice Holmes: I didn't understand what you were reading from.

Mr. Williams: "A simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired."

This was the caution to the public. The patentees could not try the process with every one and every oil. That was altogether out of the question. As a matter of fact they tried it with oleic acid and the ore of Broken Hill, Australia, and they disclosed what they did under those circumstances, and then they said: Caution. You must make a preliminary test with every oil and every ore to find out what quantity of oil you need and what oil you need to carry out the process—what oil will do it.

So to that extent this Court in the Hyde case passed upon the question of discrimination between oils, and how the public was to be guided in following the disclosure of the patent in extending the use of the process to other ores with other oils.

Now in this case we have proved, as we contend, indubitably, that fuel-oil and kerosene, separately and together, are not mineral froth-forming oils with defendant's ore. That is the proposition that we set out to prove, and we do not need to carry it further. And there was no contradiction, no effort to show to the contrary. The defendant did not in its mill at any time make any effort to demonstrate that it could produce any results whatsoever by omitting the pine-oil, which did the work, but carried on in its mill these operations with this mixture, and produced the same froth-concentrate that it had produced before by the same means, and the same machines, practically—everything the same except the pouring in of these useless oils.

Mr. Justice Brandeis: Was there any effort made to show that they could use a smaller quantity of pine-oil by adding other oils in larger quantities?

Mr. Williams: There was no experimentation at all except just that experimentation when they were trying to avoid the decision of this Court.

Mr. Justice Holmes: When they poured in the others, they had to put in a little more pine-oil?

Mr. Williams: They had to use a little more pine-oil, yes.

Their operations for two years, successful operations, the best they ever did, with pine-oil alone, a pound and a half to the ton, demonstrated what could be done with pine-oil. Now to that they added these useless oils and a little more pine-oil to take care of it.

Mr. Justice Brandeis: They made no attempt, so far as appears, to do it with less pine-oil than they had used before?

Mr. Williams: Absolutely no.

* * *

ARGUMENT OF WILLIAM HOUSTON KENYON

Mr. Kenyon: May it please the Court, it will be my function to bring the discussion back to the one real issue—

Does the defendant infringe?

Has it respected the decision of this Court when it merely adds to a process otherwise admittedly infringing, and for the sole purpose of evading the patent, a mass of functionless oil—functionless to achieve or even to assist the process, and having no effect whatever except to harm it?

Is the substance of the invention taken by the defendant, as that invention has been defined by this Court in contrast with the prior art?

Mr. Justice Pitney: I gather from the argument of Mr. Bull that he does not claim it is a functionless oil; it is part of a functioning mixture.

Mr. Kenyon: I so understood it.

Mr. Justice Pitney: You are going to discuss that?

Mr. Kenyon: I shall discuss that.

First, as to the contrast, the prior art processes, as this Court defined them, does the defendant use any one of those processes? If it does, that is the end of this case.

This Court divided the prior arts processes into two classes, which it denominated "surface flotation process" and "metal-sinking process"—those two. What the defendant is doing is not the first. This Court defined what that was, saying that that *Surface Flotation Process* of the prior art operated by lifting the mineral particles chiefly by *the buoyancy of oil* and obtaining on the top of the pulp a resulting floating *"oil"*—and I quote the language of this Court—*"Impregnated or loaded with the metal* and metal-bearing particles."

No one really pretends that the defendant is using that process of the prior art. No one so argues. The buoyant lifting force in water of the total oil used by the defendant, even if it all went to the mineral, which it does not (for about half of it, according to the evidence, runs out with the tailing) would not account for the lifting of 1% of the mineral matter that is lifted.

Is the defendant's process, the "metal sinking process" of the prior art as defined by this Court, with its operation of *agglutinating*, sticking together, the mineral particles, and as a result, the forming of granules *which settle and sink* and are taken off at the bottom? No one in the record says that it is that process. No one here so argues. Although the Circuit Court of Appeals, in the instant case, says that defendant gets the same froth that Cattermole got. But Cattermole got no froth at all. What rose in Cattermole was lost. What sinks in defendant is lost.

That exhausted the prior art by definite finding of this Court, and the defendant's present process belongs neither to the one class of those two nor to the other.

It is a *glaring error of law* for the defendant to stand here and argue that it uses *prior art quantities*, that is to say, to compare mere quantities of oil *apart from functions and processes*, and yet that is what the Circuit Court of Appeals in the instant case has done, and what the defendant here argues. It is glaring error of law, unless this Court really defined the patentees' invention as a *mere saving of oil in an old process, a mere avoidance of waste*, which of course it did not do. And yet in defendant's brief from beginning to end that is the definition of the invention ascribed to this Court—*the mere avoidance of waste.*

In sharp contrast to this defendant's process *is* the patentees' process in all its essential features.

Let us see. First, it utilizes this novel *bubble modifying function of oil* referred to by this Court. No one denies that.

Second, it lifts the mineral particles through the pulp by the buoyancy of air bubbles in the way ascribed to this invention by this Court. No one denies that.

Third, it obtains as a result the froth-concentrate described by this Court as "consisting of air bubbles modified by the presence of the minute amount of oil used and holding in mechanical suspension 70 to 80%" of the mineral matter.

So far from denying this, defendant's expert witnesses asserted, and the District Court found, that these were the facts. The Circuit Court of Appeals did not find otherwise.

The defendant argues and the Circuit Court of Appeals found in the instant case that this Court had held that the invention has *no substance except mere avoidance of waste of oil in an old process*, and that defendant does not avoid that waste but courts it and so does not infringe, and defendant cites the damage that the fuel-oil and kerosene do to its process as evidence in support of its argument. And the defendant argues, and the Circuit Court of Appeals found in the instant case, that all oils function alike; that all oil processes are alike; that all produce froth and the froths are all alike; and that the only quality required of oil by the patent is preferential affinity for the mineral matter over the gangue.

Now that argument and those findings of the Circuit Court of Appeals misconceive the decision of this Court, misread the patent, and disregard the testimony of defendant's own witnesses and the facts.

First, as to the decision of this Court. This Court held that the patentees' process differed in kind from all prior oil processes; that it utilized a novel function of oil never known to exist before; that it proceeded by a novel air-lift never utilized before, and resulted in a froth-concentrate so different from the products of other processes, as this Court said, as to make it a patentable discovery.

Secondly, this Court also held, and I quote, "That it was well known that oil and oily substances had a selective affinity or attraction for, and would unite mechanically with, the minute particles of metal and metallic compounds found in crushed or powdered ores, but would not so unite with the quartz, or rocky non-metallic material, called 'gangue'."

So *that* was not the novel function of oil in the invention, although it is a necessary function.

Thirdly, this Court held that the patent must be confined to the results obtained as specified by it, namely, the novel froth-concentrate, and this necessarily and inevitably imported and implied the bubble-modifying function of oil that is necessary to obtain that result. An oil that does not have that power with a given ore, or has it in insufficient measure, and cannot obtain that result with that ore, is necessarily to that extent excluded by that decision.

Defendant's argument on this question of preferential affinity being the *only* function required in oil, for the accent is on the "only," misreads the patent. The preamble, in stating the object of the invention, gives the general class of reagents referred to, but does not distinguish within that class. Moreover, the words "which have a preferential affinity for mineral" etc. qualify not the word "oils" but the words that follow—"fatty acids and other substances', as if it said "oils, and fatty acids and other substances that, like oils, have a preferential affinity." The limitation "having preferential affinity" etc. cuts out some of the fatty acids, because there are gaseous fatty acids and there are soluble fatty acids; and it cuts out some of the other substances, but it does not cut out any of the oils. All oils have preferential affinity. This point is illustrated by the difference between the claims. The "oil" claims do not have that language in them—"preferential affinity," etc.—claims 9 to 12, inclusive. The "oily substance" claims do have that language in them—claims 1 to 3.

Defendant's argument really is, not that the oil must have the power of preferential affinity—there is no contest about that—but that *no other power of function is necessary.*

Now Cattermole oil must have the power of agglutinating, as well as the power of preferential affinity. Given both, the *mineral* will be agglutinated and not the gangue, and hence concentration at the bottom.

Similarly, why must not the oil, in the process in suit, have the power of frothing as well as the preferential affinity? Given both, the mineral is caused to form into a froth, and not the gangue, and hence concentration.

The specification of the invention in the patent, like the decision of this Court, *features the rising of the mineral in the form of a froth.* It is the keynote of the whole description.

And every claim is either in terms or by force of the disclaimer (that is, claims 9, 10, and 11), expressly limited to causing that result, that is, *causing the mineral to form a froth.*

And therefore the patent, like the decision, calls for, and requires, that power and function in the oil and excludes any oil that does not possess it.

And the specification warns that some oils may not answer with some ores, and prescribes a simple preliminary test to determine which oils will answer and in what quantity they should be used. This Court has decided that that is sufficient.

Finally, defendant's argument and the Circuit Court of Appeals' holding as to this matter overlooks the evidence and the facts. I will refer simply to one witness, an expert for the defendant, Prof. Taggart, of Yale, who tried to explain to us out there in Butte why this flotation process floated, and being asked what was the function of oil in it, said, "The oil in the agitation-froth process seems to have two functions; first, to aid in the formation of a stable froth; second, to act as a selective agent for the separation of the sulphide from the worthless rock."

The first it achieves by its bubble-modifying function. The second by its preferential affinity for the mineral matter. Both necessary. Both fundamental. But an oil that cannot achieve the first, the frothing function, cannot achieve the process, is not an oil of the process.

In any given case it is *a question of fact* whether a given oil with a given ore under all the conditions of its use has or has not the two functions referred to.

The question of fact arises here, not as to defendant's pine-oil, which admittedly has both functions, but as to its fuel-oil and kerosene, by which it boosts up its total oil quantity to a little above 1% to evade the decision of this Court, as it understands it.

Now what does the defendant's fuel-oil and kerosene in fact do in its process?

The District Court found that it does nothing, Mr. Bull to the contrary notwithstanding. The District Court found that it does nothing toward the operation of the patent, and worse than nothing. And since that is denied, just let me read from the opinion of the District Court a few words, at page 101 of the record:

"From the evidence it appears," says Judge Bourquin, "the larger part of the oil used by defendant"——

That is the fuel-oil and the kerosene, which is more that three-quarters——

MR. SHERIDAN: He does not say which oil, does he?

MR. KENYON: Which is more than three-quarters; it is nearly seven-eighths of the total oil used.

"——and all in excess of a fraction of 1% on the ore, if not inert is ineffective, wasted, and injurious to the process and results."

Then he explains that pine-oil so much, fuel-oil so much, kerosene so much, were used, and continues:

"As before stated many oils are ineffective to operate the process and that is because they have not the quality that contributes to bubble-making."

And also lower down on the page:

"The other factors the same, it is obvious the excess petroleums in the mixture are responsible for the poorer results.''

And a little lower down.

''The addition of the excess oil no more adds to or changes the process, no more avoids infringement, than would the addition of milk or other useless substance not a part of the process.''

Mr. Justice McKenna: What did he find or decide they were used for?

Mr. Kenyon: No use.

Mr. Justice McKenna: What were they used for by the defendant?

Mr. Kenyon: To evade the patent.

Mr. Justice McKenna: Is that what the court said?

Mr. Kenyon: That is what the court said, and that is what the defendant's counsel said in argument there. ''Like a burnt child we dread the fire.'' They say it here —that it is merely to evade the patent. They add 18 pounds of an oil without which their process is better than with it. For two years they had been using the pine-oil alone, about two pounds to the ton of ore. During the three months here in question they increased that two pounds to about three pounds and ran in about 18 pounds of this fuel-oil, etc., which they had never used before in any quantity. Mr. Bull was mistaken about that. Mr. Bull was mistaken in saying that in the time prior to January 7, 1917, the defendant used petroleum. It did not. It used nothing but pine-oil alone. (Mr. Bull dissents.)

Now the Circuit Court of Appeals seems to have reversed the District Court on this fact, and yet, as it seems to me—and I will come to that in a moment—its decision was really not based on that.

But the evidence overwhelmingly supports Judge Bourquin's finding of facts.

I will just touch upon three or four headings of that evidence.

First. The defendant itself, for several years, had used pine-oil alone on the same ore and in the same quantity, about two pounds, and the work of the process was done and it was fully done. Its presence, therefore, in defendant's mixture sufficiently accounts for what happened.

Secondly, as to fuel-oil, etc. Fuel-oil and kerosene have never been used alone in the mills of the defendant; that is, without an oily frothing-agent—for example, pine-oil—or in the mills of any other company in attested and successful operation with any ore. When they tried they failed. Defendant's witness Engelmann, of the Ray Consolidated company, says, ''We tried at different times to run on straight fuel-oil, but we could never maintain metallurgical results.''

Thirdly, the practical effect of the adding of the 18 pounds of fuel-oil and kerosene per ton of ore was, not to increase the mineral frothing action or the ore concentration, but to diminish both, and to the extent of diminishing the profit from the whole operation by 12%. This is convincing evidence that the 18 pounds of fuel-oil, etc., does not take part in the fundamental operation of forming the mineral into a froth.

Fourthly, this testimony was confirmed by our presenting at the trial a test in open court by a witness who was cross-examined. We took the defendant's fuel-oil and kerosene in an amount equivalent to 18 pounds to the ton of ore; added it to the ore-pulp and agitated it. Nothing came. The result was not obtained. Then we added to that what corresponded to three or four pounds of pine-oil per ton of ore. We agitated again. Mineral-froth! That was the test, the simple preliminary test prescribed by our patent, and it showed, and would have shown to anybody, that that fuel-oil and that kerosene on that ore (it might be all right with some other ore) is not an oil of this process.

Again, the defendant's witness, Prof. Bancroft, who also tried to explain this process to us out there, analyzed defendant's mixture, or characterized its components, this way: The fuel-oil, he said, is a ''viscous non-frothing oil.'' The kerosene, he said, is ''the typical non-frothing oil.'' And the pine-oil, he said, is the ''frothing oil.''

And these professors advanced what they called the ''adsorption layer'' theory as explaining this phenomenon—this process that has revolutionized the metallurgy of the world, and yet we do not know why it all happens. They went on the stand for defendant to present this adsorption layer theory, which had to do with layers so thin—we asked how thick is the adsorption layer you are talking about in the bubble. (There is one such layer on the outside of the water film of a bubble and one on the inside of the water film where the air contacts are.) Three one-hundred millionths of an inch, he said, would be about the thinnest. And another professor referred to the forces as ''rather small forces.'' Indicating that only a microscopic amount of the oil anyway really is effective in the operation.

Now this addition of the 18 pounds of fuel-oil did not change the defendant's process one iota from the point of view of substance. The same operation proceeded by the same forces of nature in the same way to the same end after as before.

It is futile to cite the utility of minute amounts of fuel-oil with other ores when employed in connection with the oil-frothing agent of this patent. Many of our licensees do that. Why is it futile?

1. Because the evidence is clear and uncontradicted that a minute amount of that oil is sufficient for the purpose in question. One to three pounds of that fuel-oil is all that anybody uses anywhere for that purpose and the purpose is not to form a froth, but to cause a froth that something else forms to hold slightly larger particles of mineral. So they need not grind the ore quite so fine. They find that when they put in a little of this fuel-oil it makes, in a sense, a better kind of froth, a froth that will hold mineral particles a little larger, so that it is an improvement.

Mr. Justice Pitney: By increasing the preferential affinity of the oil, or how does it do that?

Mr. Kenyon: I do not know how it does it. I won't speculate. There is no explanation of why it makes the froth more—some of the witnesses call it stabilizing the froth. Our witness, Mr. Higgins, who probably knows more about this flotation than any other man alive, says it enables the froth to hold slightly larger particles of the mineral than if not used. That does not account for the use of 18 pounds of fuel-oil per ton of ore. Nobody the world around uses that amount for that purpose.

Mr. Justice Clark: Up to a certain point it improves the process?

Mr. Kenyon: Yes, up to a certain point. That is the testimony of our witnesses. It gives them a better kind of froth, a stiffer or more compact froth, or something.

Mr. Justice Clark: What is the percentage?

Mr. Kenyon: From one to three pounds. The percentage of recovery is better.

Mr. Justice Clark: Is better?

Mr. Kenyon: It is better. That is, the larger particles that might be lost are held, or you can save on your grinding, as I said, by having it all a little coarser.

Mr. Justice Pitney: Is that true of all substances? Is it true of this particular material that we are dealing with at the Butte mines?

Mr. Kenyon: That is the next point I am going to make.

2. There is no evidence in the case at all that fuel-oil has any such effect upon the Butte & Superior ore. They never used it. They didn't use it. They did not use it before, during the years that they were using pine-oil in small quantity, although they knew of its use elsewhere. We may conclude from that that it has no such effect on that ore.

3. This is not a froth-forming operation anyway. It merely improves the froth. And yet that is the sole basis —what I have just explained is the sole basis for the repeated statements in defendant's brief that the fuel-oil and kerosene are not inert or inactive in defendant's process. The whole point is as immaterial on the issue of infringement as the use of sulphuric acid that is recommended in the specification of the patent as an improvement. Sulphuric acid does not create the preferential affinity of oil for mineral, but in some occult way it enhances that preferential affinity. That question and the patent for it was what was at issue before the British House of Lords. Sulphuric acid does not make froth; does not create the preferential affinity but it enhances both.

It is no answer to say that other documents than the patent in suit refer to other petroleum oils, and describe them as frothing agents. For this is not a question of law. It is a question of fact. What work does this fuel-oil, etc., do in the defendant's process?

It is no answer to say that the petitioners are estopped here from arguing infringement by what they said in the Hyde case. For there the things under discussion were not the things under discussion here. We talked there of the behavior of 36 pounds of oleic acid, 72 pounds of cotton-seed oil, both oils of the process, every one-tenth of 1% of which was capable of doing the whole frothing work. That was a different question. Here we have now a peculiar mixture that presents a brand new question.

Really the Circuit Court of Appeals reached its conclusion because of its erroneous view of the decision of this Court.

I must jump right to the matter of disclaimer.

Mr. Justice Day: Before you get to that, is this pine-oil, as you call it, the only oil that will do this?

Mr. Kenyon: Oh, no. There are many others—eucalyptus oil. There is a whole range of oils that are excellent for that purpose. In Australia they use eucalyptus oil. Oleic acid is one oil. Cotton-seed oil is another.

The Chief Justice: You don't use petroleum? Petroleum may do it to some ores? You mention them in the patent.

Mr. Kenyon: Not in our patent, but in the British patent. With some ores they may do it.

Mr. Justice Day: Your point is that with this particular ore it does no good?

Mr. Kenyon: It does no good.

Mr. Justice Day: It is just bulk.

Mr. Kenyon: It is camouflage. The only question of fact that we have to consider is as to defendant's ore. We make no general proposition. We do not stand here and say that no petroleum will do it with any ore.

Now as to the disclaimer.

They say this Court said that claims 9, etc., were too broad because they included the use of any small quantity of oil. That was what Judge Bradford had said when he held claim 9 invalid a month or two before this Court did. He said it was invalid because it was not limited to the use of 1% of oil. This Court, with that before it, shifted the ground of criticism and said, as we judge from the context, that it was invalid because not limited, not confined, to the results obtained by the use of oil in these critical proportions.

So looking to the matter of results in the claims in question we find this to be the fact: Claims 9 to 11 differ from all the other claims of the patent in that they leave out the words "to cause the mineral matter" before the words "to form a froth", and the disclaimer practically reads that limitation "to cause *the mineral matter* to form a froth" into the claims.

The Chief Justice: We will have to stop here.

Mr. Kenyon: Thank you.

India, during the 50 years ending with last year, has imported and retained £253,000,000 ($1,226,000,000) of gold—say one-ninth of the world's production during that period. As India has also imported and absorbed in this half-century the biggest share of the silver output, the amount of precious metal which it has assimilated, notwithstanding the exiguous individual wealth of its population, is really astonishing.—Weekly Report of Samuel Montagu & Co., London.

Chalk production of England is between 4,000,000 and 5,000,000 tons, with an approximate value of 10½ cents per ton. The output for 1913 was 4,458,126 tons, worth £213,479, of which 2,796,857 tons came from the county of Kent. Essex county was second with 835,769. —R. B. Ladoo in April report of U. S. Bureau of Mines.

Treatment of Complex Ores in Idaho

[*]The treatment of Idaho ores involves several problems, but those that seem to be of greatest importance are (1) concentration of the complex lead-zinc-iron ores, and (2) treatment of gold-silver ores that are not amenable to straight amalgamation.

The first group is well represented in the Coeur d'Alene region, Shoshone county, and in the Wood River district, Blaine county. Under this group might be included, however, the deposits of the Lakeview and Blacktail districts in Bonner county, and those of the Clarke Fork district in Bannock county, as well as such lead-zinc-iron and lead-zinc-copper ores found in other parts of the State, as are separated with difficulty by the usual methods of gravity concentration.

Where the lead-zinc-iron ores are as finely disseminated as those in the mines of the Pine Creek, Nine Mile, and other districts of the Coeur d'Alene, to make clean products of lead and zinc by gravity methods is next to impossible. It has been found in examining material finer than 200-mesh under the microscope that some of the lead and zinc particles were still mechanically combined. Although at most mills a large percentage of both the lead and the zinc content is recovered in the concentrate from the jigs, fine grinding is essential to liberate the minerals and make a clean separation, with finely disseminated ores of this character. Owing to this fact, considerable amounts of zinc in lead concentrate, and no small amount of lead in zinc concentrate, is lost by the present methods of concentration. The question arises, therefore, as to whether a closer separation of the minerals is commercially feasible. Possible improvements in methods and equipment to effect a closer concentration are discussed in detail in the Bulletin under mill practice in the Coeur d'Alene region, such as finer grinding, larger flotation plants, fine grinding and differential flotation combined, preliminary roasting followed by flotation, or some hydro-metallurgical process.

To avoid radical changes in the mills, and in the local methods, it would seem advisable, if possible, to effect a better separation by differential flotation, with whatever changes in the existing methods of treatment this might necessitate. It is along these lines, therefore, that the U. S. Bureau of Mines, in co-operation with the University of Idaho and mine operators of the State, has been experimenting and will continue to do so.

Under the second group would come the gold ores of the Boise Basin region in Boise county, the Atlanta district in Elmore county, the Silver City and De Lamar districts in Owyhee county, the Seafoam and Greyhound districts in Custer county, and the central Idaho district, which is mainly in Idaho county.

The Boise Basin region, comprising the Quartzburg, Grimes Pass, Elk Horn, Idaho City, and other local districts, has many mines. In this region a large quantity of gold and silver ore in quartz or altered granite-gangue, said to average between $7 and $10 per ton, is available. The future of the region depends largely upon the successful solution of the serious milling and treatment problems which now confront the operators. The material worked in the earlier days in this region were principally free-milling gold ores, and all the plants were stamp-mills of the gravity type, with straight amalgamation. With depth, the ore gradually became more base, and table concentration and cyanidation were added to the process. Stamp-milling will now only save 50%, and much of the gold remaining in the ore is lost because of inadequate milling facilities. Thus far, only the concentrate has been subjected to cyanidation. The ore is still crushed in the original stamp-mills, and most of the mills are out of date and are making poor recoveries.

The history of the treatment of gold ore in the Silver City and De Lamar districts, Owyhee county, has been similar to those in the Boise Basin region. In the upper levels of the mines the ore was chiefly oxidized vein material, and included much material that was free-milling. Rich silver-chloride ore and lead-silver ore supplied much of the production from certain properties. As greater depth was attained the ore became more base, and could no longer be profitably amalgamated. This necessitated changes and alterations in the mills, especially the addition of cyanide-plants, and during the later years of activity in these districts practically all of the ore was cyanided. The costs of mining and treatment were always high in the Silver City district, largely because of the high cost of transportation and supplies. This resulted in a large quantity of ore of milling grade, partly oxidized, being left in some of the old stopes and on the old mine-dumps. Much of this material could probably be re-worked at a profit by proper milling methods. Considerable development is now under way in the district, tunnels being driven to intersect the orebodies at depths of 500 to 1000 ft. below the old workings. If ore in payable quantity is found at these greater depths there will be urgent need for metallurgical advice regarding proper methods of treatment. The problems involved will probably be confined to correct methods of grinding and cyanidation.

In the Seafoam and Greyhound districts, the ores comprise several distinct types, the principal ones being gold-bearing pyrite in quartz veins, associated with considerable arseno-pyrite and antimony sulphides, and complex ores containing mixtures of chalcopyrite, argentiferous galena, and auriferous pyrite, associated with arsenical and antimonial sulphides. The hauling of concentrate from this district would not be practicable under present facilities, but experiments in cyaniding these ores would seem desirable, because the district contains some high-grade ore which could be mined at a profit if haulage costs were eliminated.

---

[*] Abstract from Bull. 166, 'A Preliminary Report on the Mining Districts of Idaho', U. S. Bureau of Mines, 1919, by Thomas Varley, C. A. Wright, E. K. Soper, and D. C. Livingston.

From these general statements it can be readily seen that the chief treatment problem for the complex and low-grade gold-silver ores is to determine the best method of milling, followed by cyanidation, or cyaniding direct, according to the metal content and character of the ore, in order to effect a high recovery and to produce bullion, thus eliminating the cost of haulage as much as possible. Many prospects and properties throughout the State await further development of their orebodies and the additional capital for making changes in the mills necessitated by the increase of sulphides in the ores, which are no longer free-milling. If the treatment problems of these ores were solved, many old properties might be re-opened and the production of gold increased.

There are other ore-dressing problems connected with the ores in this State that need attention, such as are encountered in the concentration of lead, zinc, and gold ores, also of molybdenite, tungsten, and manganese ores; but the main purpose of solving the many problems is to effect a higher recovery of the valuable mineral on a commercial scale, whether the ores are complex or low-grade.

Oxy-Acetylene and Electric Welding on Dredges

[*]The Canadian Klondyke Mining Co. operates three (the fourth is out of commission) large dredges near Dawson in the Klondike, and in its machine-shop has a good deal of repair work to undertake. A complete plant for the generation of oxygen and acetylene gas from chemicals was installed and in operation since last fall, together with a complete line of oxy-acetylene welding equipment and tools, including compressors for the purpose of storing gases under pressure in low-pressure cylinders constructed for that purpose. A valuable addition to this plant, and one which will largely decrease the cost of manufacturing oxygen gas, is now being completed by the installation of 10 Vulcan electrolytic cells for the manufacture of this gas from water by electric current. The present cost of oxygen gas approximates 15 cents per cubic foot. On completion of the new machinery this cost will be reduced to less than 1 cent. A valuable by-product from this process will be hydrogen gas, which can be stored at no additional expense, and which will be extremely valuable in connection with many uses in the welding and machine-shop. The installation, as an adjunct to this department, of an electric-arc welding-plant, consisting of a suitable direct-current generator, with a complete line of electric-arc welding-supplies, has also been made; and has been in operation for a number of months whenever the necessary power was available. In addition to repair work during the operating season, the above-mentioned equipment places the company in a position to operate throughout the entire winter with both electric-arc and oxy-acetylene torches on dredge-bucket reclamation work, and on all repairs where the welding and putting-on tools can be utilized to advantage. The total cost of this installation to date amounts to the sum of $12,757.

It is not too much to say that the value of the repairs and reclamation work accomplished by the welding department to date, if credited to that department, would already offset the major portion of the investment. With this equipment it will be possible to reclaim and place again in service over 120 dredge-buckets that have been cast aside as unfit for further service at an expense which will approximate less than $150 per bucket. As the landed cost of these buckets at the present time is almost $1500 each, the resultant possible saving can be appreciated more readily.

A campaign of dredge-bucket reclamation has been arranged for the winter months, in connection with which a course of investigation is being conducted by the receiver as to the practicability of erecting a one-ton unit electric furnace for the melting and re-manufacture of scrap steel into bucket-lips, bushings, etc. In view of the excessively high cost, unsatisfactory delivery, and heavy investment charges that the present market presents to the management in the matter of steel dredging repair-parts, such an installation is being taken under the most serious consideration. To give a small idea of the convenience and saving possible to be effected by the welding-plant installations, the following may prove of interest:

On June 6 last it was necessary to close down the Hunker pumping-station owing to a bad crack in the main controlling-valve. This part could not be replaced here, and to bring one in from the manufacturers would have meant the loss of many weeks and consequent decrease in production of many thousands of dollars. The repair was made by the company's oxy-acetylene welder at a total cost of $237, and the pump started, with total lost time of 34 hours and 4 minutes.

The de-plating and building-up of the faces of a lower tumbler of a dredge will serve as an illustration of the saving effected by this process:

	Former method	Welding
Cutting out countersunk rivets (labor).	$56	$14
Material for shims..................	180	80
Labor	155	50

The cost by the welding method would be reduced still further by using scrap steel for the building-up material.

Each barrel of oil burned under the New Cornelia power-plant boilers in Arizona yields 305.6 kw. net of alternating current to the switchboard.

---

[*]Abstracted from report of the receiver, and manager, H. G. Blankman, for the Canadian Klondyke Mining Co. for 1918.

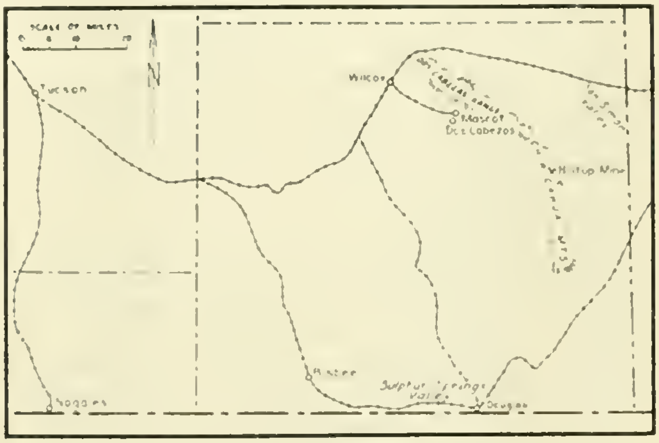
REVIEW OF MINING

TUCSON, ARIZONA

GEOLOGIC AND MINING INVESTIGATION IN SOUTH-EASTERN ARIZONA.

The University of Arizona, through the State Bureau of Mines, is offering an 8 weeks' summer course in field geology and mining in the Chiricahua and Dos Cabezas mountains, south-eastern Arizona. The class begins on July 1 and ends on August 18, and will be supervised by C. J. Sarle and M. Ehle, respectively, professors in the Departments of Geology and Mining Engineering, of the College of Mines and Engineering. It will be open to students of all universities and colleges who have had a course in physical and historical geology and mineralogy. The class is limited to sixteen and, if more apply, the selection will be made from those best qualified. The work will include geodetic and topographic surveying, mapping of areal geology, making of geologic cross-sections, studying mines or prospects and undeveloped ore deposits, and making mine examinations and reports. Maps and bulletins covering the area studied will be prepared by the professors in charge of the party, and will be published by the Bureau of Mines. Students sufficiently advanced may collaborate in the preparation of the reports, and data secured may be used in the preparation of theses. For the satisfactory completion of the entire course six university credits will be given.

The region chosen for the work lies in the Chiricahua and Dos Cabezas mountains in the south-eastern corner of Arizona. These ranges are connected fault-block structures situated in the Arizona Highlands region, an eastward extension of the Great Basin province. They are flanked on the east by the broad flat-bottomed San Simon valley and similarly on the west by the Sulphur Springs valley. They rise from fringing piedmont slopes at 4500 to 5000 ft. above sea-level, attaining over considerable areas, especially in the Chiricahua range, an elevation of between 7000 and 8000 ft. The upper reaches of the latter are heavily forested. The sharp relief of these mountains has favored rapid erosion and the carving of many deep and picturesque canyons, in which the formations and structures are splendidly revealed. The formations range in age from pre-Cambrian to Quaternary, and include a great diversity of igneous, sedimentary, and metamorphic rocks. Of the sedimentaries, the Paleozoics predominate. Several horizons are richly fossiliferous, and parts of the area are highly mineralized. The ore deposits are of several classes, and include some instructive examples of secondary enrichment. A few mines are being operated at present, although a larger number are idle on account of the metal situation. The Hill Top mine in the California district, northern Chiricahuas, now operating, has been opened by seven tunnels at different levels, in all of which ore occurs; and a tunnel nearly a mile in length pierces the crest of the range, establishing communication with canyon roads approaching the mine from opposite sides. The King is another operating mine in this district. The so-called Gold Ridge in the Dos Cabezas district, southern Dos Cabezas, transects that range, and mining and milling are being carried on from both sides. The Mascot is a well-known mine in this district. From the foregoing it readily may be seen that an opportunity for the study of all practical phases of geology, seldom realized within the compass of a single area, is presented here.



PART OF SOUTH-EASTERN ARIZONA

Although the inter-montane valleys of southern Arizona are very hot in the summer, the area selected, owing to its considerable elevation, affords almost ideal summer climatic conditions. The magnificent tree-shaded canyons, some with spring-fed streams, and the higher forested region furnish exceptionally fine camping-sites. Good roads traverse the valleys, and branch roads, passable for autos, developed mainly by the cattlemen and miners of the region, lead into all the more important canyons.

The University will furnish a full field equipment, including housing, camp cook, surveying instruments, and conveyances. Other field expenses will be met by charging each student a reasonable fee. The party will assemble at the University of Arizona on June 30 and will leave Tucson by train on the afternoon of July 1. A brief stop will be made at the copper centre of Bisbee. Here the students will have an opportunity to study some of the formations that will be encountered in their later work, and will examine mines and ore deposits in this important district. From Rodeo, New Mexico, the party will go by automobile to the first camp. Applications must be received by June 1. For further details address: The Director, Arizona Bureau of Mines, Tucson, Arizona.

BISBEE, ARIZONA

WORK AT THE SHATTUCK, DENVER, AND CALUMET & ARIZONA.—MANGANESE-SILVER ORE.

Fire-fighting in the Shattuck-Arizona's No. 1 stope on the 800-ft. level, started in February, is not yet complete, although it is hoped that during the next week or two the complete flooding of the lower workings up to the 700-ft. station will be reported. The loose nature of the ground has made flooding difficult, but at last reports the water in the shaft was about 25 ft. below the 700-ft. station. Thirty-eight bulkheads were built before water was turned in. The underground force consists of 50 men, most of whom are engaged on the fire, and in such repair work as the upper levels require.

The Denn-Arizona company is cutting a station on the 1800-ft. level. Recent developments on the 1600-ft. level, where carbonate ores were discovered, augur well for the 1700 and 1800-ft. levels. The 1700-ft. is being driven toward the ground.

The Calumet & Arizona company is raising the Campbell shaft at the present time. The head-frame, hoist, and surface buildings have been in place for several months. Ventilation underground is excellent. This was accomplished by raising an air-shaft from the 1400 to the 1300-ft. levels, alongside of the double-compartment working shaft. The draft thus created resulted in an unusually good air current. The main shaft now is above the 1300-ft. level and will be continued up to the 800-ft. level. Within the next few months it is expected that work will be started on the shaft at the surface to meet the raise. An underground hoist operates the cage that has been installed in the shaft to carry the workers up and down. The C. & A. is continuing to drive on the 1400 and 1600-ft. levels at the Junction shaft, and both drifts are reported to be in promising ground near the Denn-Arizona line.

The Boras lease, on the Don Luis side of the Mule mountains, is exploring on the 300-ft. level to get under the extensive orebodies opened at 210-ft. Beneath the old inclined shaft on that level was the same formation from which more than $25,000 of ore was shipped last year to the Copper Queen smelter at Douglas. More than 300 ft. of silicious rock, carrying small gold and silver was passed through before the copper ore was opened.——The A. B C. company has resumed sinking its main shaft after being quiet during the War. It has small but good machinery. Both the A. B. C. and Boras are under the active management of the Hon. Harry Jennings.——The Wolverine-Arizona holdings, on the south side of the Mule mountains, also are being developed by shafts and tunnels with a few men.

The Black Eagle mine at Patagonia, owned and operated by Pearce and Gardner, is shipping regularly at the rate of 400 tons per month of a manganese-silver ore to the El Paso smelter. The ore is desirable as a flux. The average silver content is 50 oz. Costs, including mining, freight, and smelter charges, amount to $15 per ton.

CRIPPLE CREEK, COLORADO

GENERAL NOTES ON THE DISTRICT.

Dividends were paid on May 10 by the Cresson, $122,000, and the Golden Cycle, $45,000.

Prospecting by diamond-drill for the lost Farrel vein has been started on No. 7 level of the Mary McKinney mine by James Ahearn, the drilling expert, under contract with the company. Ahearn has been very successful in this work at the Cresson company's Raven Hill estate.

The Rocky Mountain Leasing Co., T. A. Auter superintendent, commenced shipping during the past week from the Deadwood mine of the United Gold Mines Co. on Bull hill.

Operations have been resumed on the property of the Blue Flag company, on the north-west slope of Raven hill. The shaft now 1100 ft. deep is to be sunk to 1400 ft. by the company.

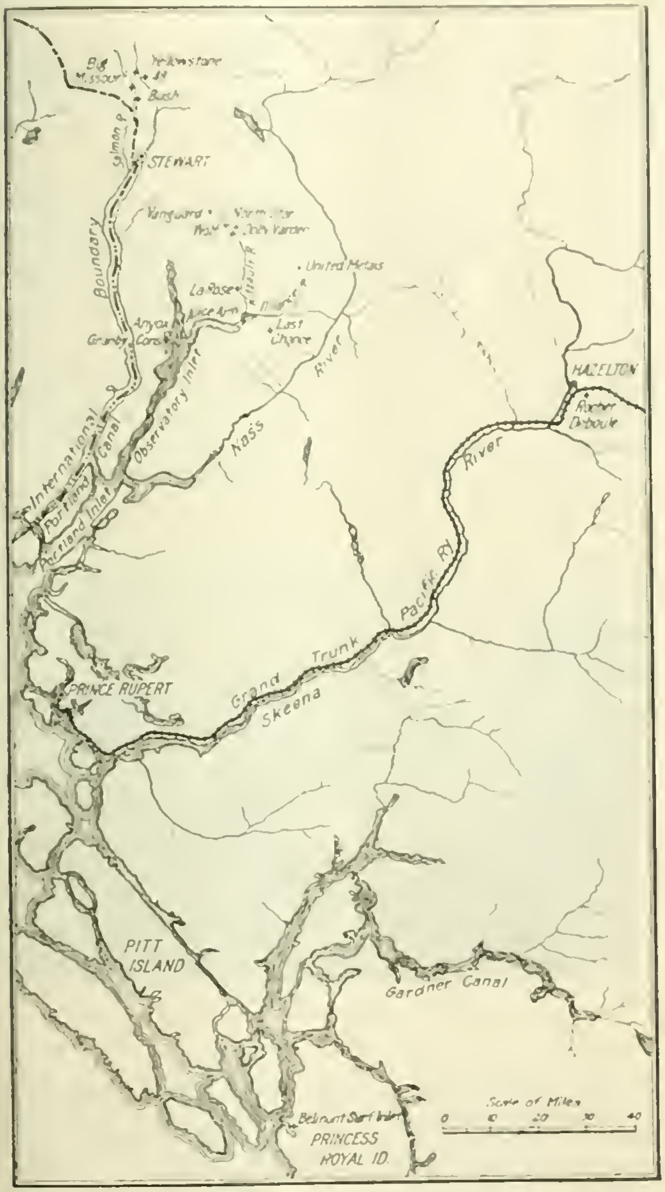
ANYOX, BRITISH COLUMBIA

SILVER MINING IN THE ALICE ARM AND OTHER DISTRICTS.

According to D. J. Hancock, who operates the United Metals Co. on the Illience river, and the Independent Two, Three, and Four on the Kitsault river, development is progressing steadily with promising results in the Alice Arm district, although the railway difficulties that have interfered with operations at the Dolly Varden are much regretted. He expects renewed activity at that property when the tangle is straightened. At the time work ceased there, diamond-drilling in No. 2 tunnel had exposed 40 ft. of high-grade ore to a depth of 600 ft. In the main tunnel there was ore of good value, while in another and shorter tunnel ore had been extracted containing silver sulphides and native silver. The Wolf mine, Mr. Hancock stated, was recently sold for $50,000 cash. Diamond-drilling there has proved the existence of a large body of high-grade ore, and a lode has been traced 87½ ft. On the Vanguard there is a 20-ft. vein of chalcopyrite exposed for 300 ft. on the surface, and $180,000, which was offered the owners for the property, has been refused. The Last Chance and North Star, both in this district, are also said to be looking well. The La Rose mine recently shipped 35 tons of ore to the Trail smelter, and obtained an average of 38 oz. of silver per ton. At the United Metals during the past year development has been carried on to determine the extent of the orebody by open-cuts and small tunnels. Seventy-five tons of ore, which Mr. Hancock expects to go 300 oz. of silver per ton, has been sacked ready for shipment. In the Independent a tunnel has been driven

120 ft. This property is only 1500 ft from tidewater, and contains silver. The ore is treated by the Granby company at its Anyox smelter free of charge because of its fluxing qualities.

Attention continues to be directed to the Premier mine, on the Salmon river, which shipped 205 tons to the Tacoma smelter, returning $67,181 gross. The Premier was formerly known as the Bush, and is owned by R. K. Neill of Spokane, and Woods and Trites of Fernie. Several important mining deals have taken place recently in which Portland Canal properties were the issue. New York men are said to have acquired a considerable interest in the Bush mine. The Forty-Nine and Yellowstone groups have been bonded to C. F. Caldwell for $125,000. The Silver King group, adjoining the Joker, has been bonded by O. B. Bush of Vancouver for $100,000. Mining properties now working in the Salmon River region are the Premier, Mineral Hill, and Joker. Work will commence by July on the Big Missouri, recently bonded to Sir Donald Mann, the Yellowstone, Bush mines, Forty Nine, and Silver Creek. With a considerable number of prospectors going into the country this summer, and with operations under way at the properties mentioned, not forgetting road and wharf construction planned by the Government, Salmon river should be the scene of much activity during the next few months. Mr. Caldwell, who is very enthusiastic about the district, expresses the hope that the Government will aid development by a railroad.



PART OF BRITISH COLUMBIA, SHOWING THE NEW SILVER AND OTHER DISTRICTS

HAZLETON.—The New Hazleton Gold-Cobalt Mines company, whose property is on Rocher de Boule mountain, has received the results of a test on 27 tons of ore sent to the testing-plant of the Department of Mines at Ottawa. An analysis gave 1.21 oz. gold, 1.12% cobalt, 1.40% molybdenite, 8.98% arsenic, 0.60% nickel. The arsenic, cobalt, nickel, and gold were intimately associated. The lot was divided into three parts, each of which was treated by a different method. The total actual recoveries were 77.6% of cobalt, 87.5% of nickel, 84.9% of arsenic, and 83.5% of gold, in table concentrates; and 54.4% of molybdenum in flotation products. The molybdenite is of secondary value compared with the other minerals. From the test work conducted, the Department reported, the procedure to follow on concentration of this ore would be as follows:

The crude ore broken in a jaw-crusher to 1½ or 1 in., ground in a wet ball-mill in circuit with a classifier to about 40-mesh, concentrated on tables of the Wilfley type, the table tailing re-ground in a ball or tube-mill to 100-mesh in circuit with a classifier, the molybdenite recovered in an oil flotation-unit, and the tailing from the flotation-unit concentrated on slime tables or vanners. Nicholas Thompson of Vancouver is president of the New Hazleton company.

SURF INLET.—In the report of the Belmont Surf Inlet Mines for the 10 months ended December 31, 1918, the following appears written on March 26, 1919:

F. W. Holler is superintendent, with H. J. O'Connell in charge of the mine, and F. H. Penn at the mill. Metals sold realized $744,432, of which $274,169 was net profit. Current assets total $422,811, and liabilities $67,107. A dividend, the first, of 5 cents a share, $125,000, was paid in April 1919. Development amounted to 1887 ft., costing $15.12 per foot. The labor conditions prevented greater footage, but results were satisfactory for new ore. Reserves are calculated as 422,761 tons of all classes, an increase of 153,790 tons, plus 116,349 tons milled. The mill treated 273 tons daily, working 93.7% of the possible time. The total concentrated was 83,142 tons, averaging 0.481 oz. gold, 0.3114 oz. silver, and 0.2606% copper, equal to $11.12 per ton. Recoveries were 91.52%, 90.23%, about 100%, and 92.13%, respectively. Concentrate, 7198 tons, contained 36,606 oz. gold, 23,364 oz. silver, and 433,399 lb. copper. Operating costs were $4.83 per ton, plus 18 cents for sundries. The hydro-electric plant works well, delivering power at $0.002268 per kw-hour.

THE MINING SUMMARY

ALASKA

Kennecott.—The Kennecott Copper Corporation last year produced 60,994,757 lb. of copper and 684,779 oz. of silver. The most important development was the finding of a new orebody on the 600-ft. level of the Bonanza mine, and another at 900 ft. in the Jumbo mine. Operations now are at 30% of capacity.

Nome.—The Fairbanks station of the U. S. Bureau of Mines has completed concentration tests on the antimony ore from the Sliscovitch mine near Nome.

ARIZONA

Bisbee.—Calumet & Arizona produced 3,150,000 lb. of copper during April, somewhat more than half of full capacity.

Globe.—A special meeting of shareholders of the Barney Copper Co. is to be held on June 2 to effect a consolidation with the Porphyry Copper Co. The new company is to be called the Porphyry Consolidated Copper Co., having a capital of $500,000.

Oatman.—Shareholders of the Tom Reed Gold Mines Co. recently met at Kingman and elected directors for the ensuing year. During the past year there was milled 84,000 tons of ore, the average recovery being $9.36 per ton, and cost $5.58. This cost was considerably below that of previous years. Little of the ore treated came from the recently opened orebody in the Bald Eagle claim.

The Lexington cross-cut from the 250-ft. level has entered the vein for 6 ft., 2 ft. of which assays $15 gold per ton. The vein closely resembles that of the United Eastern and Tom Reed. It is reported that a contract is to be let to drive a 550-ft. drift east from the present workings, which will pass 100 ft. below the old 225-ft. shaft.

The United American Company, whose property is south of the Tom Reed, is preparing to sink to 500 feet.

Prescott.—The Boxer silver mine in the Black Canyon district has been sold to the Silver Zone Mining & Milling Co. for $10,000.

Yuma.—Water shortage for the King of Arizona Mining Co., operating in the Castle Dome mountains, has resulted in a dam being constructed in a near-by canyon.

CALIFORNIA

Bakersfield.—Oil production of the State during April averaged 279,154 bbl. daily from 8726 wells. This is about 500 bbl. more than in March. Stocks increased 57,322 bbl. to a total of 32,543,145 bbl. Forty new wells were brought-in with an initial yield of 10,920 bbl. per day.

Coram.—The Balaklala Consolidated Copper Co. is suing the Mammoth Copper company for settlement on ores shipped by it during part of November, December, and January. The tonnage was 18,000, and sum involved $40,000. A preliminary settlement was made on the basis of 15 cents per pound for copper, but the Balaklala wants the balance of a price of 18.39 cents.

The Balaklala company closed its mine completely on May 13. Normally, 200 men are employed, but latterly only 40 were on the payroll. Daily shipments to the Mammoth smelter at Kennett were 300 tons, but the Mammoth had asked that these be increased. There has been difficulty in securing enough laborers, as lumber and shipbuilding pay higher wages and so attract these men from the copper districts.

The Balaklala company has raised wages by 50 cents a day, restoring the scale effective to February 16. Miners will now receive $4.50; helpers, $4.25; shovelers, $4; and surface men, $3.75. Mechanics will also get the 50-cent increase. This news was given by the manager, S. A. Holman, on May 15, some days after it was announced that the mine would have to be closed.

Downieville.—The Gold Exploration Co. of Salt Lake City, has acquired the Alhambra, Sovereign, and Comet quartz mines, and is arranging for work on a large scale. The properties are in Jim Crow and Ladies canyons.

Hemet.—So far as the general situation in the magnesite industry is concerned, there has been no marked change from the quiet conditions prevailing during the past five or six months, according to W. C. Phalen in the April report of the U. S. Bureau of Mines. This industry is linked intimately with other large industries like those of steel and copper, in which magnesite is used in furnace linings, and to the building trade.

PLANT AT HEMET MAGNESITE MINE, RIVERSIDE COUNTY, CALIFORNIA

Kennett.—Locomotive crane-men downed tools on May 15, following the action of the mechanics last week. Without crane-men it is not possible to load ore. Two furnaces are in blast, but when the supply of ore runs out they will be stopped.

The smelter was closed on the 17th.

The Reid gold mine at Old Diggings will continue shipments of ore to the Kennett smelter, notwithstanding the shut-down. The ore, which is needed as a flux, wil be put on stock-piles. The Reid employs 60 men.

Melones.—The Carson Hill Gold Mining Co., with a capital of 250,000 $1 shares, of which 185,914 have been issued, has been listed on the Boston Stock Exchange. The company is controlled by interests in the American Zinc, Lead

& Smelting Co., Pond Creek and Island Creek Coal companies. The board of directors consists of E. A. Clark, W. H. Coolidge, G. L. Stone, W. A. Ogg, and W. J. Loring. Through its subsidiary, the Carson Hill Gold Mines, Inc., the company owns 344 acres of land. The company has opened over 10,000 ft. underground. One shoot on the two lower levels is 160 ft. long and averages $24 per ton. On March 16, 1919, ore-reserves amounted to 201,830 tons, valued at $3,014,153, of which $1,999,933 would be profit.

Since the beginning of the year, the 20-stamp mill has treated the following:

	Tons	Value	Expenses	Profit
January	2,250	$30,081	$10,098	$16,985
February	3,450	41,948	20,591	21,356
March	5,100	70,781	30,478	40,304
April	6,000	....		47,500
Total	16,800	....	....	$126,145

A. D. Stevenot is superintendent.

Portola.—Surveys are being made for an aerial tram from the Walker copper mine to Spring Garden, a distance of 8 miles. At present, concentrates and supplies are trucked to Portola on the Western Pacific, which is 25 miles away.

San Francisco.—Owners and operators of chrome, manganese, pyrite, and tungsten mines who expect to file claims for reimbursement under the War Minerals Relief Act must see that such claims reach Washington, D. C., not later than June 2. The State mineralogist, Fletcher Hamilton, has just received a message from Senator John F. Shafroth, chairman of the Relief Commission, asking the co-operation of the Mining Bureau in giving further publicity to this fact. Blank questionnaires and full instructions may be obtained upon request by letter or telegram, from the Register, U. S. Land Office, Customs House, San Francisco. Immediate action is imperative by parties who consider that the Government should make good their losses, if they have not yet complied with the requirements of the Relief Act.

The State Mining Bureau, in order to aid development of the mining industry, is to establish permanent branch offices at Auburn, in Placer county, and at Redding, in Shasta county. C. A. Logan will be in charge of the former, which includes the Mother Lode and Sierra Nevada counties as far north as Plumas; while E. Huguenin will be in charge at Redding, for the eight counties north to the Oregon boundary.

IDAHO

Kellogg.—One furnace is in blast at the Bunker Hill & Sullivan smelter here, producing 90 tons of lead bullion daily.

Wallace.—Preliminary work preparatory to re-constructing the main highway across Shoshone county through the co-operation of the County, State, and Federal government, is progressing satisfactorily, according to the 'Miner'. The permanent location of the road from the Kootenai county line to Kellogg has been completed, the work being done by a party under the direction of G. I. Bassett, a State engineer. Under the agreement entered into between the Commissioners and the Highway Commission, Shoshone county will provide $100,000 for construction of the road during the next two years, and the State will contribute $50,000. With this amount secured, the Federal government, through the Forest Service, will contribute $150,000, making the total amount available for the construction of a standard road across the county $300,000. When this expenditure is made the county will be free from further expense in maintaining this highway, the State assuming responsibility for its maintenance. The most pressing improvement on the transcontinental highway across this county, an improvement that should have been made long ago, is changing the road to cross the Idaho-Montana divide at Lookout pass. This is regarded so by the State and Federal authorities, as well as by the Commissioners of this county.

MONTANA

Butte.—Anaconda pays $1 per share on May 26. This is equal to $2,331,250, and makes $8,159,375 for the current year, and $154,516,875 to date. Anaconda last year sold metals for $102,586,541. The profit from all sources was $20,802,870, $13,000,000 less than in 1917. Dividends totaled $17,484,372, a decrease of $24,000,000. The output was 293,603,726 lb. of copper, 10,967,905 oz. of silver, and 64,317 oz. of gold. The reduction works treated 4,350,446 tons of ore.

NEVADA

Battle Mountain.—Roads between Battle Mountain and the Maysville district have been opened after being blocked for five months. Heavy shipments of silver ore are arriving from the Kattenhorn and other mines.

Cherry Creek.—This old silver district is quite active again. From his lease on the Exchequer, J. W. Walker is shipping ore averaging $66 per ton.—F. W. Fletcher has resumed work on the Black Metal and will start shipping shortly.—Salt Lake City capital is developing the famous Tea Cup, and opening old workings.

Divide.—In the Tonopah Divide mine the drift south-east from the main cross-cut on the 475-ft. level is out 300 ft. Samples taken at 5-ft. intervals for the first 110 ft. average $148 per ton for the width of the drift, according to A. J. D'Arcy, the consulting engineer. The next 140 ft. is low-grade, as the drift left the hanging-wall and at one point went well into the foot-wall. The last 50 ft. assayed from $30 to $50 per ton. Two raises are being driven from the fourth level. The big air-compressor is being erected.

Since the boom started at Divide, men who have made the trip from Goldfield every week, have always passed from one to three Goldfield houses being moved to Divide; while every day for this period at least one house has been on the road. If such movement continues to the Cactus field, Goldfield will be soon de-housed.

Tonopah.—Production of the district last week, including 420 tons from the Divide, totaled 6738 tons, valued at $114,546.

The Tonopah Extension is to pay 10 cents per share, equal to $128,280. This makes $192,420 for the current year, and $2,104,819 to date.

Wonder.—The Nevada Wonder company has taken a 40-day option on the Spider and Wasp mine from Eli Cann and David Craig. The property comprises five claims, developed to a depth of 200 ft. Considerable lateral work has been done. Equipment includes a small hoist. Medium-grade ore is exposed.

UTAH

The State Road Commission has nearly $5,000,000 available for improvement of 1500 miles of roads, many of which are in mining counties.

Park City.—In the labor trouble here, a committee from the Ontario mine has conferred with the management. So far, the position is unchanged.

Tintic.—In the labor trouble in this district, the miners arranged that committees from each mine should confer with their respective managements.

The mine operators issued a statement, blaming the I. W. W. for an attempt to cause trouble here and throughout Utah.

CANADA

Ontario

Cobalt.—The sampling-plant of Campbell & Deyell, who were to retire from business recently, has been taken over by the Provincial government, to be under the supervision of Arthur A. Cole of the Temiskaming & Northern Ontario Railway Commission.

The Coalagas company paid 12½ cents per share, equal to \$100,000 on May 1. This makes 236%, or \$9,440,000 to date.

Kirkland Lake.—Companies operating in this area favor construction of a first-class highway for motor-trucks instead of a railway. The cost of the former is estimated at less than half that of the latter, which has been authorized by the Provincial government. It is pointed out that the motor road will be more flexible than the steam road, enabling everything to be delivered right at each property. A referendum on the question is being taken locally.

Acceding to this desire, the Government has decided to construct a highway instead of a railway.

The Ontario-Kirkland's shaft is down 320 ft., the last 120 ft. being sunk and timbered in 30 days.

Porcupine.—The Government is contributing \$30,000 toward the cost of constructing a motor road from Timmins to South Porcupine and to the Dome mine. The total cost will be \$60,000. The township of Tisdale is to furnish the balance.

The Hollinger Consolidated, in a quarterly report, states that there was treated 138,260 tons of \$9.78 ore, at a cost of \$5.38 per ton. The gold realized \$1,368,980, of which \$564,684 was profit. Dividends absorbed \$246,000. Current assets total \$2,534,865, and liabilities \$185,872. The number of employees increased from 911 to 1311.

Yukon

Dawson.—According to the 'Daily News', lode claims are being developed in many parts of this Territory. At present there are 860 quartz claims held. There are some in the copper area at the head of the White river, 80 miles from Kennecott in Alaska; copper claims on Williams and Merritt creeks, at Whitehorse, and the lead deposits in the Mayo and other districts of southern Yukon. Near Dawson a great deal of exploration has been done and machinery erected. Among the lode properties of promise are those situated on Williams and Merritt creeks, on the left limit of the Yukon river, 215 miles south of Dawson. The owners are J. P. Guite, J. O. Lachapelle, and J. Viau, all residents of Dawson. The property is known as the Williams and Merritt group. The claims are located upon a contact between a coarse-grained metamorphic schist and schist of a gneissoid character. Shallow shafts have been sunk and a tunnel driven. In June 1917, about 7 tons of ore was sent to Anyox, B. C., averaging \$178.75 per ton in copper, silver, and gold. The cost was \$70.53 per ton. Owing to high cost of supplies, work was stopped in February 1919. Assays made in March of this year by the Territorial Assayer, W. C. Simes, yielded 8.09 to 12.74% copper, 1.34 to 1.60 oz. silver, and 0.06 to 0.05 oz. gold per ton. Local conditions are favorable for lode mining.

KOREA

Unsan.—The last four returns of the Oriental Consolidated are as below:

Month	Tons	Gold value	Profit
April	....	\$100,000	.....
March	21,322	103,200	.....
February	17,955	88,111	.....
January	22,212	101,771	\$6,059

Good progress is being made with the Surlbong hydroelectric project, the tunnel being holed through on February 23, and the river being turned through on March 12. The quantity of native labor is fairly satisfactory, but the quality is very inferior. Rice and millet prices are still unreasonably high, and there is an actual shortage of rice in Japan; but no means have as yet been devised by the authorities for relieving the situation. An arrangement has been made with the Tanaka Choten for the sale of gold and silver bullion, the rate for the former metal being a premium of 3.6% above the par value.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. Le Roi Thurmond is returning to Anchorage, Alaska.

Arthur L. Pearse is expected in San Francisco, from London.

G. A. Overstrom, who is now living at Pasadena, was in San Francisco last week.

L. S. Noble, consulting engineer for the Cresson company of Cripple Creek, is in Mexico.

Joseph P. Ruth, of Denver, visited San Francisco on his way from Idaho and Washington.

William C. Phalen, Mineral Technologist to the U. S. Bureau of Mines, is here, from Washington, D. C.

James F. McCarthy, manager of the Hecla mine, in the Coeur d'Alene region, was in San Francisco last week.

C. R. Olson has been appointed mill-superintendent for the Como Consolidated Mines Co., near Dayton, Nevada.

C. W. Newton, manager and director for the Consolidated Interstate-Callahan Mining Co. at Wallace, Idaho, is in New York attending the annual meeting of the company.

Andrew Walz of New York last week completed examining the Victory, Belcher, and Belcher Extension properties at Divide for Aldrich-Jackling interests, which have taken them over.

Austin F. Rogers and **Cyrus F. Tolman, Jr.**, respectively, associate professors of mineralogy and economic geology in Stanford University, have been promoted to full professorships.

Burdette F. Grant, formerly general superintendent of the Swansea mines in Arizona, is now associated with **B. M. Snyder** in engineering practice in the Security Bdg., Los Angeles.

C. H. Clapp has been appointed director of the State Bureau of Mines at Butte, which is now being organized as a part of the School of Mines. He will be geologist for the Bureau; **H. B. Pulsifer** will be metallurgist; and **A. E. Adami** will be in charge of the department of mining engineering.

W. H. Nichols, president of the American Chemical Society, which has 13,000 members, addressed the San Francisco section at the Engineers' Club on May 19. There were 187 present. **H. W. Morse** gave an illustrated talk on the manufacture of potash and borax at Searles lake, California. **L. H. Duschak** was chairman for this interesting meeting.

John R. Brownell, superintendent of safety for the California Industrial Accident Commission, has resigned to take a position with the Equitable Life Assurance Society in San Francisco. Mr. Brownell will make a specialty of group and business insurance. He will be succeeded by **Hugh M. Wolflin**, chief mine inspector for the Commission. **G. Chester Brown** takes Mr. Wolflin's place. **T. W. Osgood** has been appointed superintendent of safety for the Los Angeles district.

The U. S. Civil Service Commission announces an open competitive examination for mining accountant on June 10. The salary for grade 1 is \$2400 to \$4200 per year, and for grade 2, \$4200 to \$6000. Appointments as a result of this examination will be made on a monthly basis, but the work may continue for a year or more. The duties of appointees to grade 1 positions will be to examine the accounts of producers of minerals in connection with claims made for losses growing out of the War. The duties of appointees to grade 2 positions will be to supervise the work of a number of accountants of grade 1.

THE METAL MARKET

METAL PRICES

San Francisco, May 20

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	16
Lead, pig, cents per pound	5½—6½
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce	$115
Quicksilver, per flask of 75 lb	$82
Spelter, cents per pound	7½
Zinc-dust, cents per pound	10—12

EASTERN METAL MARKET

(By wire from New York)

May 20.—Copper is active and stronger. Lead is in good demand and higher. Spelter is quiet and advancing.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May, 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 40.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

Raymond T. Baker, director of the Mint, is reported to have made the following remarks on silver. "At $1 an ounce silver mining is very profitable; even at 85 cents an ounce. Ordinarily the silver purchases for the Mint are much less than were made in 1918; in fact the quantity handled during 1918 was 2 2/3 greater than the quantity handled in 1917. It is quite likely that the purchases of silver under the Act will extend over a period of 10 years, and also that these purchases will have the effect of keeping up the price of the metal during that period. There is still a tremendous demand for silver, from India and the Orient, and the European countries. The demand for silver will grow, I believe, with the expansion in world trade following upon reconstruction in Europe and revival of industry."

Opinions of brokers in New York and other Eastern financial centres differ as to what will be the future of silver, but they appear to agree that America must wait to see what happens in London and the Far East, both of which will be the determining factor. London prices will demonstrate the urgency of the world's silver demand.

P. D. Handy, of Handy & Harmon, says: "It is idle to speculate. I do not see any grounds for expecting, however, any fantastic price for silver." V. M. Bovie, superintendent of the New York Assay Office, says: "The decision, as I understand it, places silver on an entirely new basis and the market will be affected by any bidding that may arise. The decision can be taken at least as meaning no immediate reduction in price of silver." J. S. Scully, of Zimmermann & Forshay, is of the opinion that "We may look for a good deal higher price. But just where the movement will go it is too early to say. The Oriental demand is more than ever a factor. Anybody can ship silver to China, but imports into India are restricted by the Indian government through certain recognized channels."

COPPER

Prices of electrolytic in New York, in cents per pound

The reports of three porphyry companies for the first quarter of 1919 have been published, and show the following result:

	Nevada Con	Ray Con	Utah Copper
Operating deficit	$111,159	$211,667	$12,918
Deficit after dividends	$80,955	940,887	1,955,410
Av. received for copper, cents	13.00	13.12	12.89
Cost, cents	16.85	15.15	13.72
Cost in previous quarter, cents	19.01	19.30	16.12

Copper production of some of the large mines in April was as under:

Mine	Pounds	Mine	Pounds
Calumet & Hecla and subsidiaries	8,654,113	Nevada Con.	3,763,000
Chino	3,498,000	Ray Con.	3,650,000
Greene Cananea	3,000,000	Utah Copper	9,420,000

Copper output of 17 leading mines during April totaled 87,000,000 lb., a decrease of 3,000,000 lb. from March, and 48,000,000 lb. from last November.

LEAD

Lead is quoted in cents per pound, New York delivery.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Metal stocks in Great Britain on May 1 show a gain of 5,400,000 lb. of copper to 114,531,200 lb., 8,000,000 lb. of lead to 244,186,880 lb., 400,000 lb. of nickel to 5,750,080 lb., 200,000 lb. of antimony to 9,992,640 lb.; and a decrease of 9,000,000 lb. of spelter to 76,090,560 lb. When compared with stocks held in December, the present lot is much greater.

Eastern Metal Market

New York, May 14.

All the markets have a better tone, with demand in some of them active and prices higher.

Antimony is a little higher.

Copper is stronger and higher, with demand fairly good for all positions.

Lead is fair, with the market quiet but firm.

Tin interest in future shipment metal is stronger.

Zinc shows but little improvement, with quotations steady.

ANTIMONY

There has been little change, with demand light and the market firm at 6.75 to 6.92½c., New York, duty paid.

COPPER

The market has assumed an entirely different tone during the last week, and is much more active. To this time consumers had covered their requirements up to the middle of May, and are now apparently appearing for future needs. At any rate, demand has improved decidedly, but it finds producers firm in their quotations and ideas of values, and indisposed to book orders indiscriminately. Sales have been made of electrolytic copper at steadily advancing prices during the past week, both for early delivery and for shipment as far ahead as July, but the aggregate has not been very large. Quotations as a result of present conditions are about 15.75c., New York, for electrolytic copper for May and June delivery, with 16c. asked and obtained for July. Lake copper is held at 16c., New York, for early delivery. British Government stocks of copper on May 1 were 51,130 long tons, an increase of 2428 tons over April 1 and a gain of 23,600 tons over those of December 1, 1918.

IRON AND STEEL

The feeling is general that the result of the abandonment of any price-stabilization program is going to be beneficial to the entire trade. At a meeting in New York last Thursday, between the steel men and the Railroad Administration, the entire program of regulated prices was rescinded. The steel-makers told the railroad men that no further reductions on railroad steel would be made unless wages were reduced. One Eastern maker of large, wide plates, has advanced his price to 2.75c. per lb., or $2 per ton. Many think that prices in general will advance rather than otherwise.

LEAD

The market may be characterized as firm, quiet, and steady. The weakness apparent a week or 10 days ago has disappeared, due largely to the withdrawal of those sellers responsible for the lower prices at that time. Since then and as a natural result, other sellers found things coming their way until prices have risen to those quoted today, which are 4.95c., New York, in the outside market, with the St. Louis price unchanged at 4.60c. The American Smelting & Refining Co. did not in all this time lower its price which continues at 5c., New York, although a reduction was confidently expected at one time. At the figures mentioned some business has been done, but it has not been large. The situation is regarded as fundamentally sound, and there has been good buying by cable and pipe-makers. Stocks of lead in Great Britain on May 1 were 109,102 tons, an increase for the month of 12,556 tons. This contrasts with 49,111 tons on December 1.

TIN

The feature of an otherwise absolutely lifeless market is that more interest is being manifested by consumers in purchases of tin for shipment from either London or the Far East, after import restrictions are removed. Some business has resulted from this greater interest at prices varying from 49.25 to 50.25c. per lb. from the Far East and London respectively. Aside from this, conditions are unchanged, and the market is dull. It is stated, but unconfirmed, that American smelters refuse to quote for delivery after restrictions are removed, and the suggestion is made that some protection to these producers is involved. The London market is a little higher by about £10 per ton over last week, spot Straits having been quoted yesterday at £237 per ton. This is perhaps due to the possible nearness of the lifting of American import restrictions.

ZINC

There has been little change during the week. Quotations are slightly higher, due perhaps to a withdrawal of some small sellers or speculators, and to an appreciation of the probable fact that production has experienced a curtailment. Prime Western for early delivery is quoted at 6.05c., St. Louis, or 6.40c., New York, with July delivery held at 6.10c., St. Louis. Demand continues light with but little interest shown by galvanizers and brass makers. British Government stocks of spelter in May decreased, which is true only of this metal. As of May 1 the stocks of common zinc were 26,912 tons and of refined zinc, 7057 tons, a decrease from April 1 of 764 tons and 3314 tons, respectively.

ORES

Manganese-Iron Alloys: There is almost no business in ferro or spiegel except an occasional carload. Quotations are $150, delivered, for standard ferro, with spiegel obtainable at $33 to $35, furnace. The production of ferro during April, according to 'The Iron Age', was 16,325 long tons, and of spiegel only 2778 tons, the latter the lowest in many months.

Molybdenum: Prices are nominal at 80 to 90c. per pound.

Tungsten: The market is quiet with quotations largely nominal at $7 to $10 per unit for wolframite and scheelite in 60% concentrate. For ferro-tungsten, as high as $1.40 per lb. of contained tungsten is asked, but it is believed that a desirable firm inquiry would bring a lower price.

EXPORTATION OF GOLD AND MANUFACTURES THEREOF

The War Trade Board announced the following regulations governing the exportation of manufactures of gold, effective May 9:

All manufactures of gold, the bullion value of which does not exceed 65% of the total value, may be exported, without individual export licenses, under the special export licenses applicable to the exportation of commodities not on the Export Conservation List. The shipper must, however, state in his export declaration the bullion value of each item in the shipment and the total value of such item, and that no item in such shipment has a bullion value in excess of 65% of the total value of such item.

Every manufacturer of gold, the bullion value of which exceeds 65% of the total value, is now regarded, for the purpose of exportation, as gold bullion, the exportation of which is under the exclusive control of the Federal Reserve Board. All applications, therefore, to export manufactures of gold, the bullion value of which exceeds 65% of the total value, should be filed with the Federal Reserve Bank of the district from which the shipment is made. On such applications must be stated the value of the gold content of the articles proposed to be exported, as well as the total value of such articles.

Company Reports

Reports of the 'porphyry' companies for 1918

CHINO COPPER CO.

Property: mine at Santa Rita and mill at Hurley, N. M.

Operating Officials: John M. Sully, general manager; H. G. S. Anderson, assistant; Horace Moses, superintendent of mines; O. F. Riser, assistant superintendent of mills; G. L. Webster, cashier.

Financial Statement: revenue from metals sold was $17,089,312. The net operating profit was $3,908,222, inclusive of sundries and less other charges. The surplus of current assets is $7,327,602, a decrease of $1,468,053.

Dividends: $4.50 per share, equal to $3,914,910, making $26,403,042 to date

Development and Mining: churn-drilling on the South and South-west orebodies aggregated 15,020 ft., bringing the total to 264,748 ft. since commencement of operations. This work developed 114,528,178 tons of ore. Reserves were re-calculated, and are now 95,580,737 tons, averaging 1 63% copper; plus 882,824 tons of 1.86% on dumps; and 88,465 tons of 1.37% for experimental purposes. The steam-shovels moved 3,261,556 yards of overburden and 3,749,238 tons of ore. The cost of steam-shoveling was 69.55 cents per ton, an increase of 18 67 cents.

Production: the mill treated 3,836,400 tons, equal to 10,510 tons daily, 625 tons more than in 1917. The average copper content was 1.63%. The total ore concentrated is now 17,948,678 tons. The 278,413 tons of concentrate carried 14.25% metal. Recovery was 63.275%, a decrease of 6.041%, due to inclusion of oxide ore. Milling cost $1.37 per ton, a total gain of 33%, but only 6.08% for direct treatment, taxes accounting for the balance. The smelter output was 79,340,372 lb. of copper, a drop of 4,000,000 lb. Costs were 17.178 cents per pound, compared with 11.30 cents in 1917.

INSPIRATION CONSOLIDATED COPPER CO.

Property: mine and mill at Miami, Arizona.

Operating Officials: C. E. Mills, general manager; T. A. Donahue, general superintendent; H. W. Aldrich, assistant; Felix McDonald, mill superintendent.

Financial Statement: sale of copper realized $17,516,323. Expenses totaled $11,805,322. Depreciation written off was $750,000. Sundry receipts were $290,063. The balance at December 31, 1917, was $14,011,005. Copper on hand at end of 1918 was valued at $2,978,099. This, with the profit and balance made available $22,240,169. After paying dividends the balance forward was $12,784,433. Current assets total $19,372,943, and liabilities $3,125,161.

Dividends: No. 9, 10, 11, and 12 absorbed $9,455,736.

Development: a total of 14.88 miles were driven during 1918, making 127.85 miles to date; but 10.01 miles of workings were destroyed, making 63.90 miles, and leaving 63.95 miles open at the end of the year. No work was done for the purpose of increasing reserves. The average output of ore per man-shift was 21.5 tons.

Production: the mill concentrated 5,110,101 tons of 1.361% ore, recovering 73.02%. The copper output was 98,540,041 lb., including 1,063,464 lb. from 29,031 tons of oxide ore smelted direct. The cost per pound, exclusive of depreciation and income-tax, was 11.259 cents.

MIAMI COPPER CO.

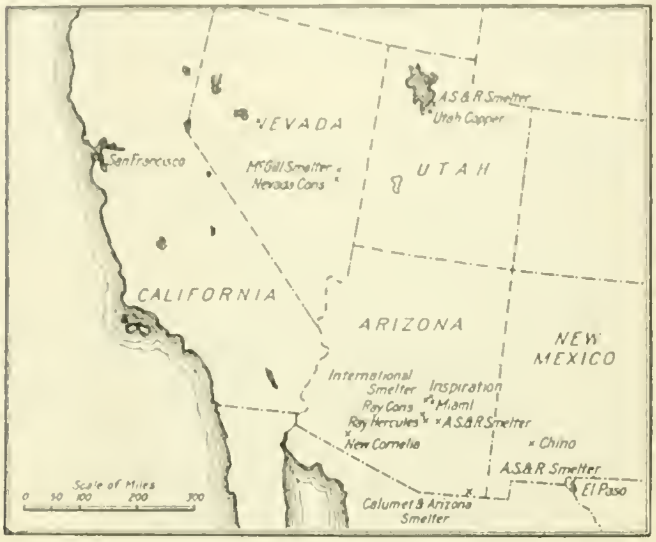
Property: mine and works at Miami, Arizona.

Operating Officials: B. B. Gottsberger, general manager; F. W. Maclennan, assistant; F. W. Solomon, mill superintendent; R. B. Yerxa, assistant.

Financial Statement: sales of copper amounted to $14,446,704. Operations and taxes cost $8,727,534, leaving a profit of $5,719,170. The average received for copper was 24.65 cents, and cost 14.83 cents per pound. Current assets total $9,625,783, including $5,103,920 for investments and securities. Accounts payable amount to $2,479,894.

Dividends: No. 22-25 absorbed $3,362,013, bringing the total to $19,595,014.

Development and Mining: underground work consisted of 10,888 ft. of driving, 3102 ft. of raising, and 882 ft. of sinking. All the exploration was on and above 570-ft. depth. No. 5 shaft is 908 ft. deep, but will be sunk to 930 ft., to provide a haulage-level and ore-pocket for the deepest ore known to exist. The shaft is being concreted. Ore extraction is by top-slicing in the main and by caving in the Captain orebodies. Ventilation was improved by re-lining No. 3 shaft with concrete. Reserves are 12,570,000 tons of 2.38%, 36,000,000 tons of 1.06%, and 6,000,000 tons of 2% mixed ores. The cost of mining was $1.36 per ton.



MAP SHOWING POSITION OF THE PORPHYRY COPPERS AND THEIR SMELTERS

Milling and Production: the plant treated 2,132,941 tons of 2.026% ore, recovering 71.15% in 76,750 tons of 40.147% concentrate. The cost of milling was 72.23 cents per ton. The total output of copper was 58,407,563 lb. The smelter returned to the company in refined form 95% of the copper in the concentrate.

NEVADA CONSOLIDATED COPPER CO.

Property: mines at Ely, railroad, and works at McGill, Nevada.

Operating Officials: C. B. Lakenan, general manager; W. S. Larsh, underground mine superintendent; F. E. Grant, shovel-pit superintendent; R. E. H. Pomeroy, smelter superintendent; G. C. Riser, concentrator superintendent.

Financial Statement: operating revenue during 1918 was $16,787,657; miscellaneous income, $1,051,694; operating expenses, $14,437,281, and profit, $3,402,071, the last item a decrease of $6,156,822. After paying dividends the balance at the end of the year was $9,934,361, compared with $13,180,526 at the beginning. The surplus of quick assets, including $6,809,668 for metals, was $11,436,904, a decline of $2,864,519.

Dividends: the total last year was $6,498,235, making $42,269,838 since the start of operations.

Development: efforts were confined entirely to production, although completion of some drilling was done at the Ruth mine. Twelve holes were drilled an average of 499 ft., and five were extended 154 ft., at a cost of $3.52 per foot. This churn-drilling cost $1.14 more than in 1917. Reserves at Copper Flat and in the Ruth are as under:

	Ruth		Copper Flat		Total	
	Tons	Copper, %	Tons	Copper, %	Tons	Copper, %
Developed to 12/31/'17	15,570,600	2.24	80,295,777	1.470	95,866,377	1.600
Added in 1918	119,168	...	2,404,680	1.360	2,523,848	1.280
Total 1918	15,689,768	2.22	82,700,457	1.468	98,390,225	1.580
Milled, 1918	2,984,724	1.98	26,855,857	1.579	29,840,851	1.619
Ore remaining	12,705,044	2.24	55,844,600	1.414	68,549,644	1.570

Of the ore mined last year, 67% was obtained by steam-shovels and 33% from underground workings. Capping removed amounted to 2,617,771 cu. yd., making 27,280,088 yd. to date. Steam-shoveling ore cost 25.88 cents per ton of ore, against 18.9 cents in 1917, and 12.42 cents in 1916. Underground mining cost 98.08 cents, a gain of 16.56 cents.

Production: the mill concentrated 3,999,526 tons of 1.506% ore, recovering 67.28%; against 4,064,095 tons, 1.462%, and 73.08% in 1917. The drop was due to lower efficiency of the employees. Total milling charges were 93.1 cents per ton, an increase of 24.5%.

At the smelter the high moisture (15.25%) of the roaster charge reduced the tonnage per furnace-day from 72.5 to 67.2. Concentrate is to be further dewatered before roasting. Four to five reverberatories reduced 654,650 tons of charge. They are fired with pulverized coal, the new plant with a capacity of 600 tons of slack coal daily ground through 200-mesh, being started in May. The yield of copper was 76,607,062 lb., compared with 82,040,508 pounds.

NEW CORNELIA COPPER CO.

Property: mine and works at Ajo, Arizona.

Operating Officials: J. C. Greenway, general manager; M. Curley, general superintendent.

Financial Statement: the income for 1918, the first full year of operation, was $11,073,680, less $6,282,500 for expenditures, leaving a profit of $4,791,180. Current assets total $4,226,205, and liabilities $2,059,522.

Dividends: an initial distribution of 25 cents per share, $351,255, was made in November.

Development: as open-pit operations had been conducted near the south-west side-lines of the developed orebody, and exploratory work had not been completed at that point, two complete and two incomplete diamond-drill holes—1825 ft. total—exposed 916,980 tons of 1.573% ore. This is all sulphide ore, the carbonate capping carrying less than 0.6% copper. A three-compartment shaft, 16 ft. 4 in. by 6 ft. inside, was sunk 250 ft., and a 7 by 9-ft. cross-cut driven to the orebody in the Southern section. A total of 2227 ft. of work was done. This orebody yielded 81,417 tons of 3.39% ore, mostly from workings at 50-ft. depth. Ore-reserves now amount to 51,320,421 tons, 80% of which are sulphides.

Production: the crushing-plant, one No. 24 and four No. 8 gyratories, reduced 1,775,000 tons of 1.465% ore. The leaching-plant produced 31,264,642 lb. of electrolytic and 10,990,666 lb. of cement copper, while metal in ore shipped direct to the C. & A. smelter at Douglas was 4,694,831 lb. The total output therefore was 46,950,139 pounds.

RAY CONSOLIDATED COPPER CO.

Property: mine, railway, and mill at Ray and Hayden, Arizona.

Operating Officials: L. S. Cates, general manager; U. S. Boyd, assistant; C. A. Smith, superintendent of mines; D. D. Moffat, superintendent of mills; R. J. Ezell, cashier.

Financial Statement: the revenue from metals during 1918 was $19,209,311, of which $4,863,455 was profit, including sundries. After paying dividends, the balance of $16,890,196 at the end of 1917, was reduced to $16,417,819.

Dividends: with $150,000 for the Red Cross, etc., the total was $5,275,832, making $20,681,084 in all.

Development: new work consisted in extending the main haulage-ways on No. 3 level, also in preparing the orebody for stoping, a total of 61,711 ft., compared with 84,915 ft. in 1917. To the end of 1918 there were 134 miles of workings opened, and 69 miles destroyed, leaving 65 miles intact. As development approached the lower levels, the men could no longer walk to their places by adits and inclined shafts, so No. 4 main shaft was sunk 547 ft., concreted, and equipped with a 37-man hoist per trip. A brick change-house of 1200-man capacity was erected. Ore-reserves are 86,383,642 tons, averaging 2.061% copper. The cost of mining 3,476,749 tons was $1.695 per ton, plus 6.5 cents for coarse crushing and loading.

Production: the mill treated 3,411,000 tons of 1.613% ore, recovering 74.92%; compared with 3,560,900 tons, 1.635%, and 74.53% in 1917; 3,332,340 tons, 1.607%, and 70.20% in 1916; and 2,848,969 tons, 1.673%, and 64.11% in 1915. The recovery of copper sulphides was 83.68% last year, the oxides reducing the total to 74.92%. Including copper from direct smelting ore, the total output was 86,919,270 lb., about 5,000,000 lb. less than in 1917. The cost of milling was $1.01 per ton, an increase of 18 cents.

The average net cost of producing copper was 17.193 cents per pound, against 12.446 cents in 1917.

UTAH COPPER CO.

Property: mines at Bingham and works at Magna, Utah.

Operating Officials: R. C. Gemmell, general manager; J. D. Shilling, superintendent of mines; H. C. Goodrich, chief engineer of mines; F. G. Janney, general superintendent of mills; H. C. Smith at the Magna and T. A. Janney at the Arthur mill; J. M. Hayes, treasurer and assistant secretary; and C. F. Jennings, assistant purchasing agent.

Financial Statement: copper sold realized $43,029,021, gold $1,018,561, and silver $477,547, a total of $44,525,129. Operations cost $30,717,827. After adding $5,138,477 dividends from other properties, and deducting $500,000 for Red Cross and war work, the surplus was $18,445,780. The surplus of quick assets is $28,512,816, a decrease of $1,773,073. The face value of investments is $13,614,116.

Dividends: $10 per share, equal to $16,244,900, making $92,015,783 to date.

Development and Mining: churn-drilling at the Porphyry mine amounted to 7625 ft. In the Sulphide mine there are now 13,989 ft. of workings accessible. This mine produced 34,769 tons of copper-lead-zinc ore. The average thickness of the Porphyry orebody is now 556 ft., an increase of 18 ft. as proved by drilling. After 79,381,400 tons of ore had been extracted from the start of operations, reserves are still 374,040,000 tons, averaging 1.37% copper. Capping moved in 1918 amounted to 4,064,091 yards, making 48,042,824 yards in all, spread over 259 acres. The total cost of steam-shoveling was 53.7 cents per ton of ore.

Treatment and Production: the Magna mill treated 18,151 and the Arthur 15,166 tons daily, a total of 12,160,700 tons. The average grade was 1.2262% copper, and recoveries 65.11%—57.89% at the Magna and 73.39% at the Arthur. Improvements to the latter are complete, but those at the former are now under way. The cost of concentrating was 92.77 cents per ton. The leaching plant treated 1190 tons daily of oxide ore, at a cost of $1.0568 per ton.

Year	Tons	Copper, %	Copper lb.	Cost per ton	Cost per lb., cents
1915	8,494,300	1.4340	156,207,370	$0.8024	6.612
1916	10,994,000	1.4350	197,417,480	0.9355	6.918
1917	12,542,000	1.3367	206,174,442	1.4170	12.708
1918	12,160,700	1.2262	197,978,557	1.7630	16.331

As the treatment plants have been described so fully in the 'Press' recently it is unnecessary here to note the many improvements.

The Bingham & Garfield railway carried 34,081 tons of ore daily, and a total of 617,749 passengers. The main line is 37 miles long, and other tracks 96 miles.

Book Reviews

Gasoline and Kerosene Carburetors. By Victor W Page Pp. 206, ill., index. Norman W. Henley Publishing Co., New York. For sale by 'Mining and Scientific Press' Price, $1.50.

Where one man was interested in carburetors twenty years ago, there are probably one hundred today Furthermore, the fact that gasoline production has failed to keep pace with consumption has increased interest in the development of carburetors for vaporizing the heavier constituents of petroleum. The present volume is non technical, and within the province of anyone with enough intelligence to run an internal-combustion engine.

Introductory Mathematical Analysis. By W. Paul Webber and Louis Clark Plant. P. 299, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, $2.

This book was written for a college textbook, and this will constitute its principal field of usefulness, although the engineer that has forgotten his college mathematics may be able to use the book as a means of refreshing his memory. The first two chapters constitute a brief review of elementary algebra and geometry. The book then deals with co-ordinates, trigonometry, vectors, conic sections, series, and differential and integral calculus.

Handbook of Mechanical and Electrical Cost Data. By Halbert P. Gillette and Richard T. Dana. Pp. 1716, ill., index. McGraw-Hill Book Co., New York, 1919. For sale by 'Mining and Scientific Press'. Price, $6.

As the preface states, this book is intended as a companion volume to Mr. Gillette's 'Handbook of Cost Data', and Mr. Dana's 'Handbook of Construction Plant'. The arrangement is similar to the former book, but there is little overlapping. In these days of abnormal prices, and of discussion as to whether or not large reductions will be made in the near future, some engineers and estimators may feel that a book of cost data, since its costs manifestly cannot be brought up to the minute, is of slight value. That this viewpoint is erroneous, provided the cost analysis is accurate and complete is shown by the authors in the first chapter.

Essentials of Alternating Currents. By W. H. Timbie and H. H. Higbie. P. 360, ill, index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, $1.60.

This book is written with the needs of men having little training in higher mathematics in mind, and will be useful to them as a text and reference book rather than to college-trained engineers. The chapter-headings are as follows: Modern Systems of Power Transmission; Power Factor; Current and Voltage Relations in Series and in Parallel Circuits; Polyphase Circuits; Calculation of Wire Sizes; Motors, Starters, and Controllers. An appendix contains a number of useful electrical tables. The book is well illustrated. At the end of each chapter there is a brief summary of the important points discussed, which would be of great assistance to the student in reviewing.

Scrap Metals. By George H. Manlove and Charles Vickers. Pp. 278, index. The Penton Publishing Co., Cleveland. For sale by 'Mining and Scientific Press'. Price, $2.

The scrap-metal industry, like so many others, was unheralded and unsung until the War directed the public attention to its importance. The present volume is the first we have seen that is devoted entirely to this industry, which handles nearly one billion dollars worth of material each year. The first part of the book, by Mr Manlove, is devoted almost entirely to iron and steel scrap, and discusses not only the scientific principles governing its use in blast furnace, steel plant, and foundry, but also the principal sources and kinds of scrap and the methods of marketing and of financing the scrap industry. As the book was written while Government control of the industry was still in force, considerable space is devoted to this topic. The appendixes contain the principal classifications and specifications for scrap The second part of the book, by Mr Vickers, is devoted to the non-ferrous scrap metals, taking up each class of metal and alloy in turn, and showing how the various articles may be sorted in order to give the best results in the furnace.

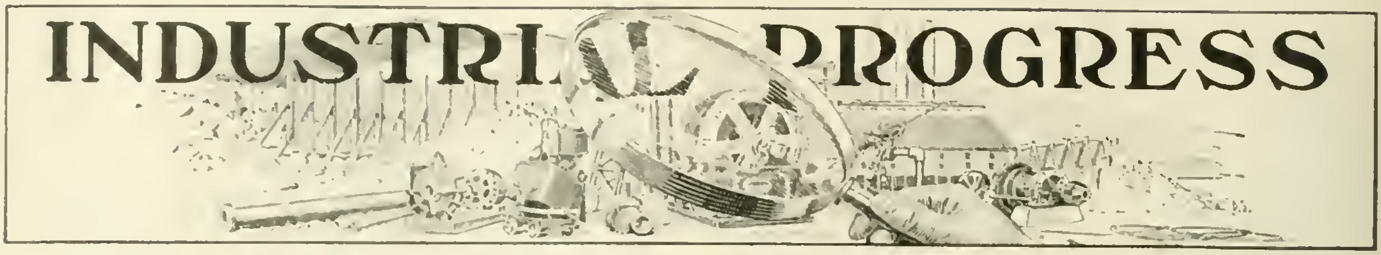
The Turnover of Factory Labor. By Sumner H. Slichter Pp 442, index. D. Appleton & Co., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, $3.

For centuries employers have been 'hiring and firing' and complaining of the cost of breaking in new employees without making any direct attempt to study labor turnover and the possibility of its reduction. In recent years, however, there has been considerable investigation and discussion of this subject. The present volume is probably the most complete that has appeared and presents the results of several years study. Most of the data given are for years preceding 1916, thus eliminating abnormal war conditions. The book first considers the various ways of expressing and measuring the turnover and then its classification under resignations, lay-offs, discharges, and miscellaneous causes. The effect of various factors on the size and rate of the turnover is then considered. Next comes the cost of turnover, both to the employer and employee. Turnover is then analyzed according to causes, the subdivisions being causes pertaining to the job, causes arising from relations between the men and the management, causes pertaining to the men, and causes pertaining to better opportunities elsewhere. The remainder of the book, about half, is devoted to methods of reducing turnover, based mainly on what certain firms have actually accomplished. While the book will appeal to the sociologist, it is thoroughly practical, and should be in the hands of employers of labor and superintendents.

Graphic Methods for Presenting Facts. By Willard C. Brinton. Pp. 363, ill., index. The Engineering Magazine Co., New York. For sale by 'Mining and Scientific Press'. Price, $5.

The man that said, "There are three kinds of lies, plain lies, damned lies, and statistics," probably had in mind, in part at least, the benumbing effect upon the brain of the average reader of a long line of figures with no means provided of properly correlating them. The fundamental idea of graphic methods is to assist the mind in visualizing the facts expressed in statistics. Yet, even here, as the author shows, care is needed, or the purpose of preparing the charts will be defeated. The book deals with the various kinds of graphic representations, including plain figures and diagrams, curves, maps, and combinations of these methods. The applications of the various methods to the domain of the engineer, the business man, the manufacturer, and the lawmaker are then discussed, particular attention being paid to the use of graphic methods for making company reports more intelligible to the average stockholder. The two final chapters are devoted to a discussion of the general methods of preparing graphical data and to the errors to be avoided in doing such work. The treatment of the subject throughout is non-technical, and makes no use of the higher mathematics. There are over two hundred illustrations showing various applications of graphic methods.

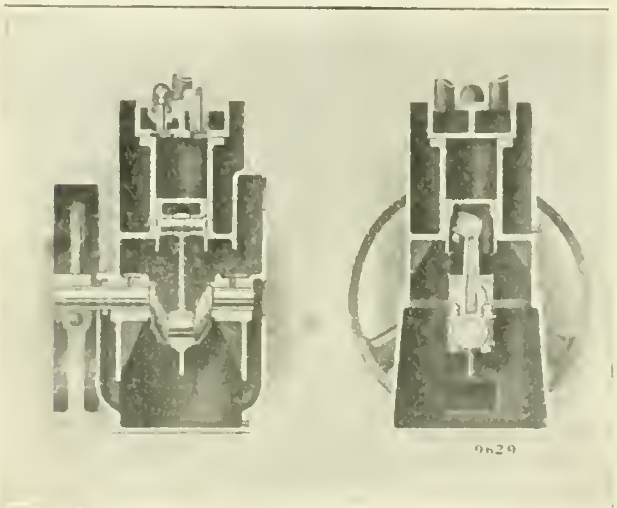
INDUSTRIAL PROGRESS



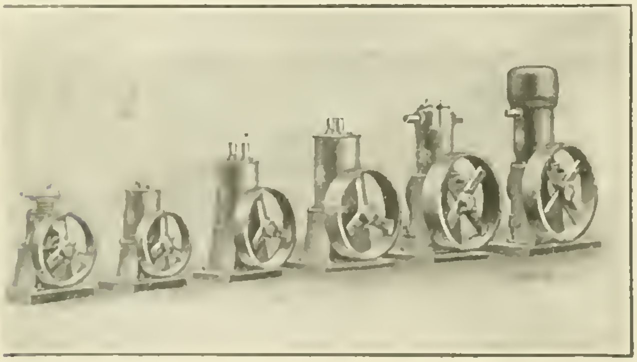
INFORMATION FURNISHED BY MANUFACTURERS

THE LATEST IN SMALL AIR-COMPRESSORS

In the emergency at the outbreak of war, there was a sudden call for a large number of small air-compressors for service where reliability was imperative, so the Ingersoll-Rand Co.'s offer to produce for immediate use the 'Imperial Fourteen Compressors,' which it had just completed testing and had adopted as the new standard small compressor type, was accepted. The field performance of these built-on-hurry-order machines was watched critically, but after a year's service their record was clear; they had proved themselves efficient, reliable, and inexpensive to operate.



Sectional View of the Imperial Fourteen Compressor



Types of the Imperial Fourteen Compressor

Now these little machines have been placed on the general market. There are four sizes, the capacity ranging from 3 to 45 cu. ft. per minute at pressures to 100 lb. per square inch. The small compressors can, however, be used for pressure requirements up to 200 lb., the power needed being, of course, slightly increased. They are single-acting machines of the vertical type, built for belt-drive. Where driven from line-shaft, tight and loose pulleys are supplied; where the use of independent motor is planned they are ordinarily furnished as a unit complete with motor, endless belt, and short-drive attachment. In the latter case a hardwood base-plate is included with the standard equipments.

The machines are so well-balanced as to operate satisfactorily if bolted to any solid flooring, but where permanency of installation is desired, the building of a concrete foundation is advocated. The smallest size is built with ribbed cylinder for air-cooling where the service is intermittent, and with water-cooled cylinder of the reservoir type for continuous operation. Larger machines are water-cooled only, employing the reservoir-jacket system except that, in the case of the largest size, a closed jacket for connection to pressure-system is optional. In this connection it is worth noting that the reservoir-cylinder design affords unusually ample water-capacity, and that both cylinder-barrel and head are cooled. The manufacturer states that a single filling of the water-space will suffice for a 10-hour run.

In general design, the Imperial Fourteen reminds one strongly of an automobile engine. There is the same drop-forged crank-shaft and connecting-rod, the die-cast renewable bearings, the automatic splash-lubrication system, and general ruggedness and simplicity which have come to be recognized as guarantees of satisfactory service under all sorts of operating conditions. It is pointed out, however, that these little units were designed to meet exacting efficiency test and that, while simplicity was sought, efficiency was the outstanding requirement.

COMMERCIAL PARAGRAPHS

Mark R. Lamb's Paris office has secured an order from the Peñarroya company of Spain for two Hardinge conical mills, 6 ft. diameter, for fine grinding in the new flotation plant, which that company has erected.

Pioneer Rubber Mills is the name under which the Bowers Rubber Works of San Francisco is now operating. The change in name became effective April 1, but the management and policy of the company continue as under the old name. The Pioneer works will continue to make all the brands such as Skookum piston-rod packing, Copper Queen belting, and Victor fire-hose. G. N. Towne is vice-president and general manager, and D. D. Tripp is vice-president in charge of sales, at 68 Sacramento street, San Francisco.

The Chicago Pneumatic Tool Co. makes the following announcements: T. J. Hudson has been appointed acting manager of the pneumatic tool sales division, effective April 15, succeeding F. H. Waldron, who returns to Minneapolis, Minnesota, as district manager of sales for the Minneapolis territory.------Allan E. Goodhue has been elected managing director of its English subsidiary, the Consolidated Pneumatic Tool Co., Ltd., whose offices are at 170 Piccadilly, London, and whose plant is in Fraserburg, Scotland. Mr. Goodhue will also be in charge of European sales for the Chicago Pneumatic Tool Company.

EDITORIAL

INFLUENZA is a subject that came home to us not long ago; therefore it will interest our readers to learn that the Sanitary Commissioner of India estimates that five millions died of influenza in that country, besides a million more in the so-called Native States, making a total mortality of six millions. The worst period was in the last quarter of 1918, particularly in October and November.

HEADQUARTERS for field-assistants of the State Mining Bureau have been established at Auburn, in Placer county, and at Redding, in Shasta county, in charge, respectively, of Mr. C. A. Logan and Mr. E. Huguenin. The State Mineralogist, Mr. Fletcher Hamilton, has been moved to this new departure by a realization of the variety of minerals disclosed by the prospecting stimulated by the exigencies of the War; he appreciates the difficulties encountered in obtaining supplies of sundry industrial and structural mineral products, and hopes, by encouraging further investigation and prospecting, to develop our domestic resources.

OUR Canadian friends appear to appreciate the need for gold. The Minister of Finance is being importuned by the Vancouver Board of Trade, at the instance of Mr. Nicol Thompson and others, to extend the existing embargo on the export of gold bullion so as to include complex ores containing gold. Much of this kind of ore is smelted at Tacoma and other points outside Canada, therefore it is proposed, as an alternative to the total prohibition of exportation, to make it obligatory to return an amount of gold equivalent to that extracted from the ore exported outside the Province of British Columbia. The idea is to increase the reserve of gold in Canada and to encourage the refining of all metals within the Dominion.

CLAIMS for compensation to the producers of chrome, manganese, tungsten, and pyrite during the War are shortly to be adjudicated. The War Minerals Relief Commission, consisting of Messrs. John F. Shafroth, M. D. Foster, and P. N. Moore, with a competent staff, will be at Little Rock, Arkansas, on June 7 and there begin the first of a series of hearings to be distributed over the various mining districts. The itinerary of the Commission will cover, in the order named, the following cities: Tucson, Los Angeles, San Francisco, Medford, Portland, Baker City, Spokane, Butte, Salt Lake City, and Denver. The route indicated thereby is from Arkansas to Arizona, thence through California, Oregon, Washington, Montana, and Utah to Colorado. It is stated that 260 claims have been filed, calling for relief to the total amount of $6,000,000. The sum appropriated by Congress for this purpose was $8,500,000.

IN our last issue we gave the depth of the Ooregum mine, on the Kolar goldfield, in India, as 5380 feet. A later report, just to hand, states that two shafts, the Oakley and Bullen, have reached the 60th level, which is 5419 feet vertically below the surface. The Ooregum exploits an ore-shoot, or series of nearly parallel ore-shoots, on its pitch northward from the Mysore and Champion Reef mines. These properties, so successfully managed by the old and honorable engineering firm of John Taylor & Sons, have been highly productive since 1883. They were first explored by white men in 1871, when an Irish soldier, named Lavelle, began to prospect on the site of ancient workings, which were 300 feet deep in places, notably on the Mysore ground. Last year this group of four companies, all under the same capable management, produced $10,029,000 worth of gold.

STOCKS of metal held in England on May 1 show the highly congested condition of the market. The copper on hand is given at 114½ million pounds, as compared with 61⅔ million pounds on December 19. Lead stocks have increased to 244 million pounds, as compared with 110 million pounds in December. A surfeit of lead is evident. At one time during the War the amount on hand is said to have been as high as 500 million pounds. Stocks of zinc and aluminum have increased from 56⅔ and 22¾ million pounds, respectively, to 76 million and 25¾ millions, respectively. The spelter is of the highest grade, meant for making munitions, and is now saleable only on a par with 'prime western'. It is expected that these stocks of the base metals will now show progressive decrease, owing to increasing consumption, and it is evident that until they are liquidated the international market cannot regain its normal absorption.

TO assist the taxpayer engaged in the oil and gas industry in preparing his Federal tax-returns correctly and expeditiously, the Bureau of Internal Revenue has prepared a manual, which is based upon the information gathered last autumn by a corps of geologists, technologists, and engineers selected from all parts of the United States. This investigation was undertaken primarily to furnish a basis for valuing oil and gas properties and for estimating the deductions to be made under the headings of depletion and depreciation. Records of production all over the country were collected and tabulated, for subsequent classification and study with a view to establishing curves of production and standards of valuation. This has been done, and the manual is available to those needing such assistance. Copies, together with the necessary blanks to be filled by the taxpayer, can be obtained from the Commissioner of Internal Revenue at Washington or from the Internal Revenue Collector of the nearest district. Every oil operator and every professional man connected with the industry ought to have a copy of the manual in his hands. The curves and tabulations are intended to guide the taxpayer in computing his allowance for depletion, which, in turn, directly bears upon, and often controls, the amount of his tax. In the event of a sale of property the valuation deduced gives the basis on which the taxation of the profit is to be computed. The Treasury Department, however, declares itself in no way committed to the acceptance of estimates based on the curves it has supplied; every claim for deduction on account of depletion therefore must be inferred by the taxpayer from the facts covering his own operations, and it must be accompanied by a detailed statement of production. Hence the taxpayer will be well advised to seek competent technical assistance in the preparation of his returns, for experience has shown that unless this is done a demand for an excessive tax is likely to ensue from inadequate appraisement, that is, a demand may be made in excess of what the law intended the operator to pay. The Treasury officials declare frankly that every operator "must make his own case," which is a fair warning to all concerned.

The Flotation Issue

Our readers, we feel sure, will have shared our keen interest in reading the arguments presented to the U. S. Supreme Court in the final hearing of the case between Minerals Separation, Limited, and the Butte & Superior Mining Company. We would have liked to publish the briefs, but they are too long for our limited space, whereas the oral arguments are of a convenient length; moreover, the latter are the more interesting on account of the colloquies between counsel and the Justices on the bench. The first argument was that of the lawyers representing the petitioners, the Minerals Separation company. We can imagine the scene, having ourselves heard the appeal made in the Ninth Circuit Court here in San Francisco. Mr. Williams speaks with jaunty confidence and with a pleasantly smooth intonation. Mr. Kenyon has a staccato utterance and gesticulates nervously. The manner of the Minerals Separation senior counsel has the reinforcement of many successes in the long-drawn litigation, for Mr. Williams has guided his clients with notable skill through a variety of courts. Anybody reading his argument will be impressed by its cogency. The validity of the patent, No. 835,120, was conceded by the Supreme Court in the Hyde case, so the issue in this case is infringement of the patent as defined by the Court. The proportion of oil requisite for the working of the patented process is the crux of the conflict between the parties. The Butte & Superior had attempted to evade the Court's decision, so Mr. Williams argues, by camouflage, namely, by adding a large amount of ineffective mineral oil to the small amount of effective vegetal oil, thereby trying to prove that the so-called critical proportion of less than 1% was not essential to the success of the agitation-froth process of concentration. This addition of mineral oil is an immediate consequence of the Court's decision in the Hyde case, on December 11, 1916. The Butte & Superior interpreted that decision to mean that the patent was confined to one-half of 1% of the oil per ton of ore and that they could use any kind of oil they pleased. In this interpretation they were sustained by the Appellate Court of the Ninth Circuit. Note the colloquy between Mr. Justice McReynolds and Mr. Williams, in which the latter denies the possibility of getting the result with more than 1% of pine-oil; and then the one between him and the Chief Justice, in which the latter infers that the process cannot be performed with more than two-tenths of 1% of pine-oil. Mr. Williams asserts that the addition of the mineral oil decreases the efficiency of the process; he claims that the use of it caused a loss of $1,000,000 profit to the Butte & Superior company in 1917. By turning to the company's annual reports we find that the mill recovery in 1916 was 93.1% of the zinc, whereas in 1917 the recovery was 91.13%, and in 1918 it was 92.96%. Such slight difference as is shown may well have been due to the strike at Butte and the decreased efficiency of the labor available after the United States entered the War. The difference in profit is to be found in the decreased price of spelter, which averaged 12.63 cents per pound in 1916 and 8.57 cents in 1917. In the interchange with Mr. Justice Holmes it becomes evident, not for the first time, that the patent applies to conditions not anticipated at the time it was granted and that an effort is being made to stretch its specifications to a new metallurgy. The thick oily liquid called oleic acid as applied to Broken Hill ores is vastly different in its physical properties from the oils now in use, and that is why so many of the claims in the patent do not accord with actual practice in the United States. Then comes Mr. Kenyon, who asserts that the defendant is not using the process of the prior art; it seems evident to us that the flotation process of today is as different from the oleic acid and Broken Hill ore method of Minerals Separation as it is different from the prior art of Elmore, Kirby, and Delprat, for example. Flotation as now used in America has been evolved from a new experience and is in many essentials a new process related as much and as little to the prior art as to patent 835,120. One would suppose from Mr. Kenyon's statements that the prior art was represented by Cattermole's patent and no other. Cattermole's process was never even tried in this country; it was a rank failure even at Broken Hill. Any comparison with it is misleading. As we read Mr Kenyon's categorical denial of a frothing function to mineral oil we recall the experiment performed before the Court of Appeals in which the kerosene used at Butte—without pine oil—yielded a splendid froth, although, according to the record, an identical experiment before the Supreme Court in the Hyde case produced only "three or four bubbles." To the onlooker it is apparent how incomplete is the evidence presented at these Court proceedings; it is always a lap behind. On the other hand, the testimony of Mr. E. W. Englemann, of the Ray Consolidated, denying the metallurgic efficacy of fuel-oil, is a noteworthy contradiction. As a matter of fact, the users of flotation know that some mineral oils produce a froth and some do not; also that the same mineral oil will undergo change so that it will function variably. What is not known about flotation greatly exceeds what is included within current technology. Mr. Kenyon concedes the fact that a little mineral oil is helpful; he does not know why; it improves the recovery, he says. Next we come to the counter-argument for the Butte & Superior. The senior counsel, Mr. Thomas F. Sheridan, did not take part; he left the presentation of his client's case to his associate Mr. Bull, a distinguished patent lawyer, who speaks quietly and clearly; his pose is that of a veteran. He started by reminding the Court that his client was using mineral oil, mixed with vegetal oil, before the decision in the Hyde case. Accepting that decision, and conforming to it, the Butte & Superior increased the proportion of oil so as not to infringe, that is, it used more than the critical proportion, "as described in the testimony and in the claims of the patent"—the words used in the Supreme Court's opinion. Mr. Bull traces the gradual decrease in the oil used, from 300% by the Elmores in 1898 to 1.2% by Cattermole in 1902 and less than 0.2% by Minerals Separation in 1905. What are the "critical proportions" as laid down by the Supreme Court in the Hyde case? On the answer to this question hinges the decision in this case. Minerals Separation has specified that the critical limits are between 0.05 and 0.02%, as quoted by Mr. Bull. He also cited their assertion that "if more oil is used, you do not operate the process, and you do not get the result." This refers primarily to vegetal oils, yet, even as regards other oils, "the process is dependent upon such definite minute amount of oil." The plain truth is that Minerals Separation did not know exactly how the oil functioned; they committed themselves to these positive statements in order to influence the decision of the Court and they are now inconvenienced by their previous tactics. Mr. Bull quoted the colloquy between Mr. Justice McReynolds and Mr. Kenyon in the Hyde case. This was cited in the Court of Appeals, on which occasion it was apparent how it made Mr. Kenyon squirm. In the course of that colloquy Mr. Kenyon gave away the case for Minerals Separation, and, it seems to us, furnished the Court ample reason for sustaining the adverse opinion of the Court of Appeals. He acknowledged that the use of more than half of 1% did not infringe. The patent specification made particular mention of a fatty acid, oleic, which is no longer used and does not enter into the comparison between vegetal and mineral oils. Again we say that the patent applied to metallurgical conditions that do not exist in current practice. Is not petroleum as much an "oily substance" as oleic acid? Has it not a "preferential affinity for metalliferous matter"? Mr. Bull pushed his argument home by showing that the first written description of the invention covered by patent 835,120 made mention of using petroleum residuum on Broken Hill ore and later the patentees used gasolene successfully. The most convincing evidence, however, is the fact that the Minerals Separation witnesses have acknowledged the use of mineral oils by their licensees, notably at Anaconda and Britannia; moreover, the proportion of vegetal to mineral oil in the mixture employed in the Butte & Superior mill is that adopted by two of the Minerals Separation licensees. That is the case for the Butte & Superior Mining Company and it seems to us a strong one. It remains impossible to predict the result; to us it appears that the Court of Appeals interpreted correctly the opinion of the Supreme Court, but the previous decisions of the various courts in the flotation litigation—the Hyde, Miami, and Butte & Superior cases—have been so discordant that no layman, and no lawyer, can forecast the judgment for which we are now waiting anxiously.

Lest We Forget

German protests against the severity of the peace terms exhibit a cynical forgetfulness of the threats they made when they expected to win the War they themselves provoked. Herr Scheidemann, for example, makes an appeal to the British people and says that he "cannot believe that fellow human beings, however much under the influence of wicked war, can really intend to reduce a kindred civilized people to slavery." The kinship did not count for much on June 20, 1915, when a representative group of German professors, diplomats, and superior government officials, posing as the spokesmen of kultur, assembled in the Künstlerhaus at Berlin, issued a manifesto in which they said: "If we found ourselves in a position to impose a war-indemnity upon England—England which has always been so niggardly in sacrificing the lives of its own citizens—no sum in money could be enough." They were predatory, those intellectuals of Berlin, but they were worse, they were cowards jibing at brave men. Let the spirits of the dead that lie in Flanders field, let the million British men that died in the effort to drive the Huns out of France and Belgium, answer the sneer that they joined to their anticipation of loot. The British were not "kindred" then! Whether they really intend to reduce the Germans to slavery, we have not been informed, but the fact is that the Germans "really" did reduce a people who would disdain to be called "kindred", but certainly were "civilized", to pitiless slavery. The pages of history for all time will damn the Germans for having kidnapped and enslaved the Belgians by tens of thousands, and all because they refused to allow their country to serve as a road into France. The less the Germans talk about slavery the better for them. Shall we so soon forget how young men were seized at night, placed in cattle-trucks, and deported to Germany, there to be forced to work under cruel conditions until they broke down physically, and either died or were returned the wrecks of manhood? A hundred thousand men underwent this treatment, such treatment as would hardly be given to cattle or swine. It was deeds such as this that turned the American neutrals of the Belgian Relief Commission, says Dr. Vernon Kellogg, "into a shocked, then bitter, and finally blazing band of men wishing to slay or be slain, if necessary, to prevent the repetition anywhere of the things they had to see done in these tortured lands." Shall we forget this now, when they whine about kindred races and civilization and throw up their hands à la kamerad? They cry out against the cession of the Saar coalfield and they call President Wilson all kinds of names because he approves the terms of reparation for their sabotage in France. What did they expect to do if they had won? In May 1915 six industrial associations, thoroughly representative of the agricultural, manufacturing, and trade interests of Germany, sent a petition to the German Chancellor, and to the governments of the various Federated States of the German Empire, in which they specified the terms of peace to be demanded. They insisted that Belgium "must be subjected to German Imperial legislation, both in military and tariff matters, and also in regard to currency, banking, and postal arrangements." .... "The government must be so managed that the inhabitants obtain no influence on the political fortunes of the German Empire .... and all economic and industrial undertakings and real estate, which are so vital for the government of the country, must be transferred into German hands." Would anything remain of Belgium by the time this program had been carried out? As to France, these German leaders said: "We should hold the French coastal districts from the Belgian frontier approximately as far as the Somme .... The hinterland, which must be acquired with them, must be so delimited as to secure to us the complete economic and strategic exploitation of those Channel-ports which we gain." That was not all. "The acquisition of the line of the Meuse and the French Channel-ports would carry with it the possession, not only of the iron-ore district of Briey mentioned above, but also the coal-country in the department of the Nord and the Pas-de-Calais"—in short, the industrial regions of northern France, together with the seaports through which their products passed. Here again the inhabitants were to have no political rights. The petition says that "these annexations must be so arranged that the populations of the annexed districts shall be precluded from exercising political influence on the fortunes of the German Empire, and all the economic resources of these districts, including both large and medium-sized estates, must be transferred to German hands." Oh yes, they were the mildest mannered gentlemen that ever cut a throat or scuttled a ship! They had their eye on the iron resources of France, having realized that when they seized Lorraine in 1871 they had overlooked a part of the spoils of war. So, on May 20, 1915, these representatives of German business urged their Chancellor to remedy Bismarck's oversight, in these words: "Hence the security of the German Empire in a future war imperatively demands the possession of the whole minette-bearing district of Luxemburg and Lorraine, together with the fortifications of Longwy and Verdun, without which this district cannot be held." 'Minette' is the name of the low-grade iron ore for which this region is famous. They summarized their demands thus: "The acquisition of territory suitable for agricultural settlement [referring to the Baltic provinces of Russia] and the appropriation of the iron-ore district of the Meurthe and Moselle, of the French coaling districts in the department of the Nord and the Pas-de-Calais, and also of the Belgian coalfields." These were captains of industry, and they naturally might be greedy, but what about the flower of German intellectuality, were they different? Not at all. We have quoted from their manifesto already. Here are some more of their high-minded demands. "We must have no mercy on France, however terrible the financial losses her own folly and British self-seeking have already brought upon her." .... "The German people consider it an absolutely unquestionable matter of honor [what a word to use in such a context!] to keep a firm hold on Belgium." .... "Russia is excessively rich in territory, and we demand that the territory which Russia is to surrender to us in lieu of war-indemnity shall be delivered to us for the most part free of private ownership." .... "We must look to other quarters of the globe also, if we are to secure adequate acquisitions." .... "Finally, as regards indemnity for the war, we naturally desire such an indemnity as will, so far as possible, cover the public cost of the war." Having outlined their modest demands, these intellectuals concluded their manifesto with a few remarks concerning "the German mind," which started the whole train of calamitous events and now bewails the consequences of its colossal crime. Recall the barbarities, cruelties, and atrocities perpetrated by German men, and women, during the War; recall the miserable mess they made of their great predatory campaign; recall the fact that they threw up their hands as soon as the fight went against them on land, and surrendered their proud navy because they feared to meet their enemy on the sea, and then read this insolent assertion of the 1341 German professors, diplomats, and officials: "The German mind is, in our opinion, beyond all doubt one supremely valuable asset. It is the one priceless possession amongst all our possessions. It alone justifies our people's existence and their impulse to maintain and assert themselves in the world; and to it we owe their superiority over all other peoples." The only reply that befits the occasion is that made by General Cambronne of the Old Guard at Waterloo; not the reply history records, "The guard dies, and never surrenders," but the one every Frenchman knows him to have made, too strong to appear in polite literature.

DISCUSSION

Justice to Our Native Young Men

The Editor:

Sir—The section of your magazine devoted to discussion has, for some time, been a deep source of interest to me, and I am, therefore, using it as a means to penetrate beneath the surface of my chosen subject and bring the matter under the close observation of the mine operators of the various districts, as I find, among the many manifestations of the spirit of intellectual anxiety which marks an important factor in the mining communities of today, is the failure, on the part of these gentlemen, to recognize the sons of the old residents of the mining districts, upon their graduation from college.

At every mining centre, both great and small, there are always a number of families who have met with sufficient success to enable them to send their sons to college to receive a professional training. After obtaining their degree, the old folks, hoping to have them near home, encourage a search for success in their home town, the place of their birth—hence very dear to their hearts. However, disappointment ensues. They find it almost impossible to obtain an opening at all worthy of their ability. By this I do not mean to imply that the mining settlements are devoid of responsible positions. Not so—there are many, the majority being held by technical men whom the operators have secured from afar, thus rendering it difficult for the native young men to return home with an expectation of progress or success at home.

Now why would it not be an honorable, as well as a just, scheme for the operators to keep a record of all the young men of their particular district, and materially aid in assisting those who have received their degrees and wish to return, by favoring them, in place of sending away for their technically trained men? Right here, we shall all agree that charity always begins at home, but whereas to some this might appear as such, I venture to state that it should simply be nothing more or less than a pledged duty on the part of the operators, as the parents, residents of the place for years, have spent both their time and money, through hardships and otherwise, in the upbuilding, as well as the uplifting of the mining community. So why should they not receive, at least, the small recompense of seeing their sons occupying the important positions at the mines and mills, thereby carrying on the good work in, possibly, a higher degree.

Then too it would be sensible to assume that these young men would prove of greater value to the mining companies than men from the outside, as naturally the entire interest of the company, as well as the district at large, is close to their heart, whereas, with the non-resident, it would be more likely to be simply a money proposition, and he would not seem so inclined to keep the "home fire burning," so to speak, or further the interests of the company or district. On the other hand, the native son, possessing a natural interest in the home district, would have at heart the best interest of the population, and where the people of a district are met with a sincere spirit they are pretty sure to practise a little reciprocity themselves, in return. So in this manner the native son would prove another ace, because he would help to promote a closer co-operation between the workmen and the managers, which is as essential to successful operation of mining companies as well as of other enterprises; so I think these suggestions might prove worthy of careful consideration, and if the fundamental values of the matter could be more clearly conceived and more directly pursued, it would drive home an affirmative conclusion with telling power.

In concluding, I might call to mind the statement so wisely made by Confucius, to the effect that the chief moral force in society is the example of the "superior man." Virtue in superiors will always call out virtue in common folks, for between man and man the rule of practice is reciprocity, which, needless to mention, is a worthy attitude toward one's fellowmen.

Warren, Arizona, May 9. M. STOCKHOLM.

Blue Sky Laws

The Editor:

Sir—The question of fraudulent promotions and the Blue Sky law has been brought rather strongly to our notice in Colorado during the past few months; first, because a Blue Sky law was proposed in the last Legislature, and (after many amendments were added) killed in committee for fear that it would interfere with the promotion of legitimate enterprises; and second, because of some promotions of large size that have not been looked upon with favor by competent engineers. In the last few months I have had the unpleasant task of disillusioning many investors in mining shares and of examining many stock certificates unearthed from the strong boxes of dead relatives. I have yet to find a valuable one, or to announce to some investor that he has a fortune. Most of the letters are pathetic. They are from people who could ill afford to lose the money the stock represents; many of them are illiterate, and not a few have given everything they own to some fraudulent promoter. A passage comes to my mind: "This man told us to mortgage our home and put the money in this company, and it would make us rich." That line is a tragedy in itself, and there are many of them. Of course the rejoinder to any complaint of this sort of thing is, "Well, they should have known better," which smacks not a little of a remark of Cain's.

Do the Blue Sky laws prevent this sort of thing? The experience with the sale of mining stocks in Kansas and Nebraska would lead me to believe that the Blue Sky law is worse than useless in dealing with mining frauds, however valuable it may be in other cases. Let me give an example. The X company (the State law prohibits my giving the company's name) organized to operate a mine in Grand county, Colorado, passed the Blue Sky law of Kansas, and I believe of Nebraska. This mine is an old one which has been long operated to the profit of its promoters. The first organization specialized on negroes, and apparently raised large sums of money in the upper Mississippi Valley. Wild statements pervade its literature, and its agents made still wilder ones. Every stockholder was a potential millionaire. The company was then re-organized, took a new name, and specialized in ministers; as soon as the harvest was reaped there, another re-organization was carried out, which is now said to be garnering the pennies of the country school-teachers. There is a mine back of the company, which does a little work. There is some ore, but, to my knowledge, none has ever been sold. In our office files there are at least a hundred letters on this one concern, upon which the good State of Kansas has set its official guarantee. There is in an old letter case of mine, the prospectus of a company with a mine at Ward, Colorado, showing steamboats ascending Left Hand creek, and receiving ore at the company's docks. Left Hand creek, by the way, has a fall of 200 ft. per mile, and is seldom more than a foot deep. This prospectus was issued for consumption in Michigan and Minnesota.

While I do not believe that the Blue Sky law is a preventive, I do believe that a law would be of great value if it would make the statute of fraud apply in the case of promoters or venders of stocks who wilfully make false statements, or conceal facts concerning mining stocks that they are offering the public.

The English Directors Liability Act of 1890 was based on this principle, and has been successful. One cannot speak too strongly of the need of some such reform. The continued promotion of fraudulent mining companies is a disgrace to the mining industry, and to those of us who are engaged in the direction of mining enterprises. Furthermore, for our own comfort, it must be said that a rigid law will increase the faith of the public in mining and mining men.

J. Terry Duce.

Secretary, State Bureau of Mines, Colorado.

Denver, May 7.

The Miner and Prohibition

The Editor:

Sir—The relation of prohibition to the miner and operator is of the greatest importance, more especially from the operator's point of view; and strange to relate, prohibition measures have been passed by many Western States chiefly through the votes of the miners themselves.

It is likewise true that a certain class of city workmen have heralded the slogan "no beer, no work!" in view of national prohibition, which it is believed will be a reality after July 1, 1919, but the miners of the West, as a class, appear to know the great danger occasioned by even one of their number under the influence of liquor—not only to himself but to the many innocent lives in contact with him—while working underground. Operators of large mines are constantly on the alert through competent foremen, shift-bosses, and time-keepers, in order to thus shield their men from the menace of this great foe.

It must be remembered that many thousands of men that enjoy an occasional glass of liquor, of varying degrees of strength or character, have gladly given up their desires in order that the man who cannot control this appetite may be cured and probably saved from a premature death, and in many cases, actually enable his pay-check to provide a living for himself and family, which otherwise frequently becomes dependent upon friends or the authorities. These are not the only classes that will be greatly benefitted, for it is most noticeable that the rich and well-to-do, from the most fashionable quarters of our large cities, and professional men of the highest standing, compose a great proportion of those that occupy the psycopathic wards of the county hospitals.

I was won over to total prohibition by witnessing the grand work it has performed in the State of Kansas, where may be seen families that have since grown up without a saloon or a drunk, or knowing or desiring the taste of liquor. Here is a new generation with brains unimpaired by alcohol. During its growth the insane asylums have been well-nigh emptied, the need of police protection largely diminished, and the work of the courts and its officers greatly lessened, thereby proportionately lessening taxes, much greater than when licenses were paid by the liquor interests, which alone created the large majority of criminals.

Hence, by analogy, we have learned that, if national prohibition becomes a reality, within the course of the next 10 years we will have lost the desire for liquor and in 30 years a new generation shall have taken our places; and they will carry on the business of these United States in a manner, I predict, so superior from that of today, that our action of today in giving up the long-established use of alcohol and in wiping out of the great liquor trust, which is putting up the greatest fight of its life, solely because of its enormous profits, would appear as nothing in the balance.

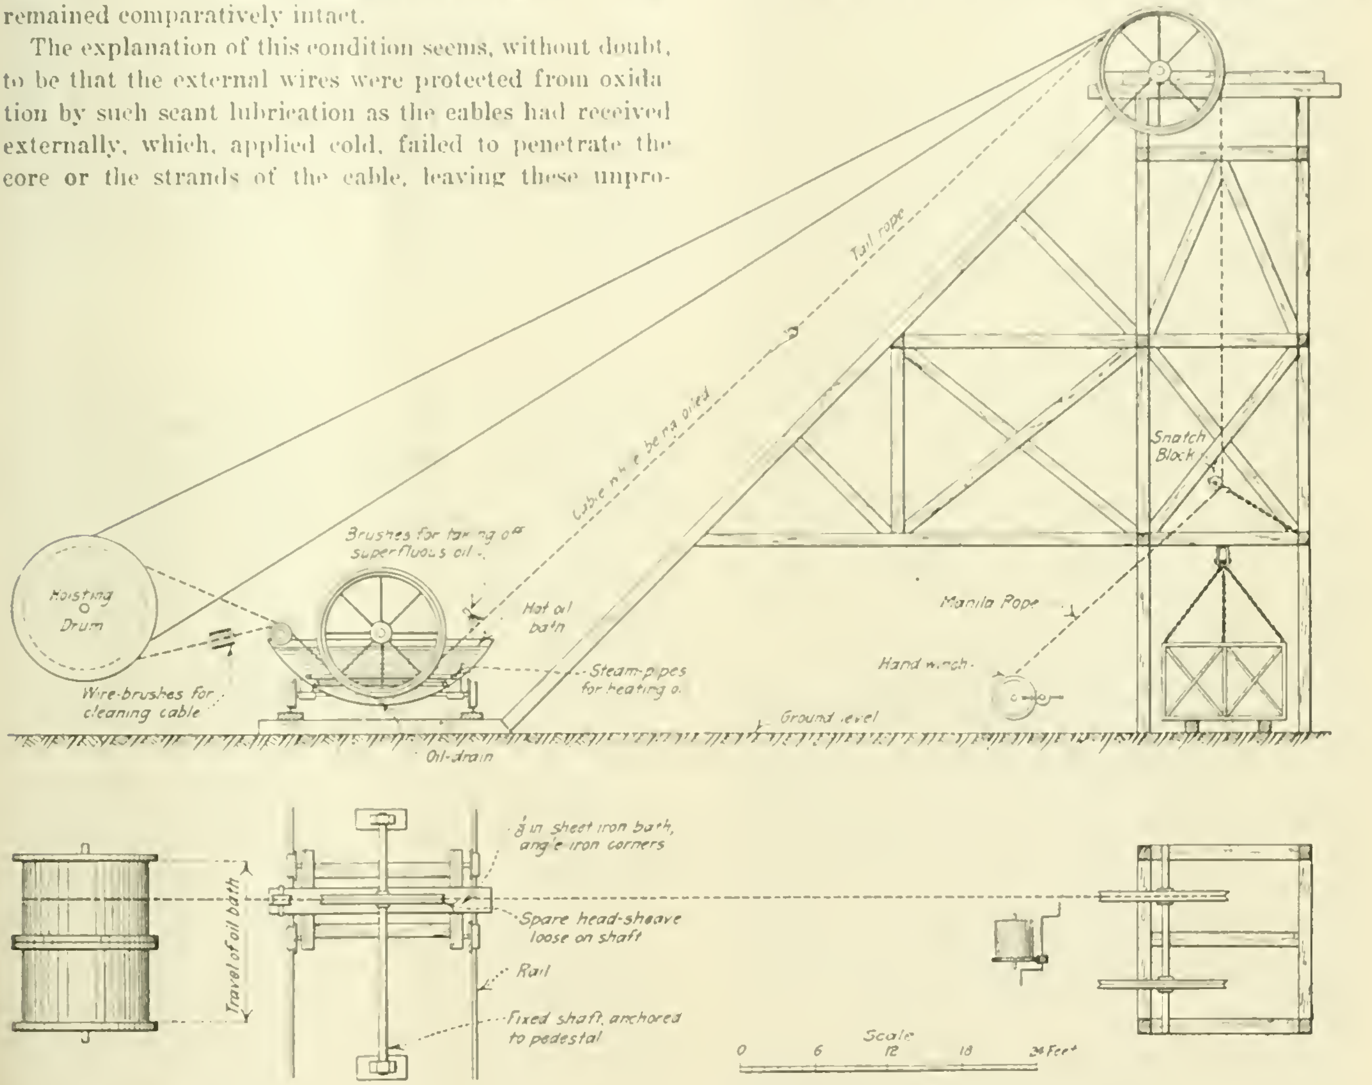
Oiling Mine-Cables in Place

By WM. FLEET ROBERTSON

*In a previous paper I have had occasion to draw attention to the destructive deterioration of certain wire cables, by reason of the excessive rusting of the wires in the interior portion of the cable, while the exterior wires remained comparatively intact.

The explanation of this condition seems, without doubt, to be that the external wires were protected from oxidation by such scant lubrication as the cables had received externally, which, applied cold, failed to penetrate the core or the strands of the cable, leaving these unprotected from the corroding action of water and damp air.



Tail rope
Cable while being oiled
Snatch Block
Brushes for taking off superfluous oil
Hoisting Drum
Hot oil bath
Manila Rope
Hand winch
Steam-pipes for heating oil
Wire-brushes for cleaning cable
Ground level
Oil-drain
⅛ in sheet iron bath, angle iron corners
Travel of oil bath
Spare head-sheave loose on shaft
Rail
Fixed shaft, anchored to pedestal

DEVICE FOR OILING MINE-CABLES

The need for oiling the interior of the cable is, first, to provide lubrication for the wires moving on one another, although my observations have not shown any excessive wear on the wires in its absence—and, secondly, and by far its most important function, to provide a protective covering for the wires to prevent oxidation.

My recent observations deal with cables of 1¼ in. and 1½ in. diameter composed of steel wires formed into strands, these strands again being wound around a hemp core, which seems to be the accepted practice in the manufacture of cables of this size.

The internal hemp core when it leaves the factory is usually saturated with grease, which thus acts as a reservoir of lubricant for the wires of the cable, and lasts for some time, for, as a strain is put upon the cable, it compresses the core, thus expelling the grease among the wires.

In a comparatively short time, this 'reservoir' becomes exhausted of lubricant, its place being taken by air and water. It seems to be the accepted and logical conclusion that before the reservoir is depleted it should be promptly renewed, if the cable is to be protected internally from oxidation, and thus such renewal must be re-

---

*A paper read before the recent meeting of the Canadian Mining Institute at Montreal. By courtesy of the author.

peated periodically. How frequently this should be done will depend upon the conditions under which the cable is being used and would probably have to be determined experimentally.

The danger lies in the false assumption that a cable once lubricated internally always remains so and in the only too prevalent practice of trusting to the outward application of a little grease or oil, usually applied cold. That this will not penetrate the strands is a foregone conclusion. It seems to be generally conceded that such penetration can most surely be obtained by the immersion of the cables for a certain time in the lubricant. As to how this can best and most easily be accomplished has elicited numerous suggestions, one of which is the placing of the cable, coiled up, either off or on a reel, in a tank of oil for some hours. Some argue that this would be sufficient to be effective, while others demand that the tank be closed and its contents be subjected to a pressure—175 lb. per square inch being suggested—a rather serious and costly procedure. A further suggestion is that the oil in the tank be also heated, and this last is, in my opinion, the only effective method.

The interstices in the core and the strands, under working conditions, become filled with air and water, which cannot be driven out by the oil through pressure applied equally on all sides. Consequently pressure alone would be ineffective, while as an adjunct to heat it is superfluous and would be very expensive. If the lubricant be heated to above 212°F. all water in the cable will be driven off as steam, while air would be so expanded as to be also expelled and into the vacuum thus formed the oil would be forced by atmospheric pressure.

This tank treatment would probably be effective and is all very well for cables as received and on reels, although not so necessary with new cables, as they are usually fairly well lubricated. If a renewal of the lubricating process is necessary, this would entail the removal of the cable from the shaft and from the drum, because coiling of it on a reel, together with its transportation to and from the tank, is a lengthy process during which the shaft must remain idle unless a spare cable is available. The whole procedure represents such an expenditure of time and money as to not be favorably considered by the mine manager.

To obviate this double expenditure and thereby ensure that cables will be oiled and re-oiled, I beg to present in the accompanying sketch an arrangement that can be cheaply constructed from materials already around most mines, whereby a hoisting cable may be efficiently oiled without removal from the drum, without delay of more than half a shift, and at a nominal expense.

The cage is brought to the surface, and there blocked on timbers; the cable is detached from the cage and attached to a manila tail-rope. The cable is then wound up on the hoisting-drum until the end of the cable and tail-rope come to the oil-bath. The end of the cable is then detached and passed through the bath and under the sheave-wheel; it is then attached again to the tail-rope by which, with the aid of a hand-winch, the cable is slowly pulled through the heated oil-bath and back to the cage, where it is re-attached and the empty cage slowly lowered to the bottom. The operation is then reversed, the whole cable passing twice through the oil-bath.

About 16 ft. of the cable would be in the bath at one time and if the cable is passed through at a rate of four feet per minute it would then have two immersions of four minutes each, which should be sufficient. The oil in the bath must be kept at a temperature of over 212°F. by the aid of live-steam pipes and it is suggested that vaseline with flake-graphite mixed through it will probably be found to be most effective and lasting.

It is essential that the cable, before entering the bath, should be as thoroughly cleaned as possible of all dirt by the use of wire-brushes. The horizontal travel of the cable in unwinding will automatically move the bath and carriage on rails and so keep it in line at all times.

The supporting shaft of the bath sheave-wheel must be anchored down sufficiently to hold the upward pull of the cable after the cage is attached.

Talc

By R. B. LADOO

*The talc business in this country is largely dependent upon the paper industry for existence, roughly 80% of the domestic talc being used in the manufacture of paper. The other 20% is divided among many different industries, some of which are paint, rubber, textile, lubricant, etc. The high-grades of talcum powder for toilet uses are made almost exclusively from imported Italian and French talc. In the paper trade, domestic talc has to compete with English clay. While in many cases it can successfully replace clay as a filler, it is not usually suitable as a coating for the best grades of paper.

During the War, domestic talc producers expected a curtailment of clay and talc imports, and anticipated a large demand for their product. But imports were not materially reduced, and an unusual demand for domestic talc was not felt. At the present time the demand for paper talc is light, and the outlook is not very promising. It is stated that all the talc mines in New York State are now shut-down. It is felt in some sections of the industry that domestic talc cannot compete with imported talc and English clay, unless protected by tariff or greatly improved methods of grinding, sorting, and screening are used.

Paper-makers differ radically in their opinions as to the suitability of talc as a filler, but talc men assert that domestic talc properly treated can in most cases be substituted for English clay and a large financial saving made. It is stated that where a 50% retention of clay in the paper is customary, there is a retention of 75 to 90% of talc. Much of the so-called grit is merely improperly screened oversize talc, and not silica.

American talc is quoted at $20 to $40 per ton.

Minerals Separation v. Butte & Superior

Hearing of the Case Before the U. S. Supreme Court. Argument for the Respondent, Butte & Superior Mining Company

ARGUMENT OF J. EDGAR BULL

MR. BULL: May it please the Court, the acts complained of in this case are the following:

Before this Court handed down its decision in the Hyde case the defendant was using one-tenth, or about one-tenth, of 1% of oil. It was using not only straight oils, such as oleic acid and pine-oil, but for a considerable time it had been using this particular mixture which it is using now; that is to say, vegetable oil and petroleum. We admit that this use was an infringement of the patent as it has been construed by this Court. An injunction has been granted against the continuance of that use, and an accounting ordered; so that your Honors have nothing to do with the use by the defendant of oil in quantities of about one-tenth of 1% on the ore.

As soon as the opinion of this Court in the Hyde case was handed down the defendant changed its practice, and thereafter it always used more than one-half of 1% of oil on the ore, and for a large portion of the time it has used more than 1% of oil on the ore.

THE CHIEF JUSTICE: Now as to the experiments made, you are assuming that the oil had nothing to do with it, and the experiments were made afterward, but the effect was produced. Counsel on the other side, who has just taken his seat, said that is a mere combination to make something appear to be something which is not something, which does not accomplish the result.

MR. BULL: I understand, and I am going to deal with that question later. I am simply pointing out now that the oil that we used at the time the opinion of this Court was handed down in the Hyde case was the same mixture—that is to say, a mixture of vegetable oil and petroleum—that we are using today.

As I say, as soon as this Court's opinion in the Hyde case was handed down we changed our practice and used larger quantities of oil, over one-half of 1%, and most of the time over 1%, of the same mixture we had used before; that is to say, a mixture of vegetable oil and petroleum. These acts are the only ones which this Court has to consider at this time.

We are here merely to construe your Honor's opinion in the Hyde case. That is all we asked the Court of Appeals to do, and that is all the Court of Appeals did. We are not here to quarrel with your Honor's opinion in the Hyde case in any particular. In fact, we are here justifying under that opinion.

As soon as that opinion was rendered we changed our practice, and it is conceded that that change of practice is costing my client millions of dollars a year in its effort to conform with what we understand to be this Court's decision in the Hyde case.

Now I shall take up the discussion of this Court's opinion in the Hyde case.

In your opinion in that case you used the following language, reading from pages 4 and 5 of my brief:

"The prior processes which we have described required the use of so much oil that they were too expensive to be used on lean ores, to which they were intended to have their chief application and the efforts of investigators for several years prior to the discovery of the process in suit had been directed to the search for a means or method of reducing the amount of oil used, and it is clear from the record that approach was being made, slowly but more and more nearly to the result which was reached by the patentees of the process in suit in March, 1905.

"The present invention differs essentially from all previous results. It is true that oil is one of the substances used but it is used in quantities much smaller than was ever heard of, and it produces a result never obtained before."

In concluding the opinion, you said:

"While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion there were many investigators at work in this field to which the process in suit relates when the patentees came into it, and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success', yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions' 'amounting to a fraction of one per cent on the ore', and therefore the decree of this Court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7, and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11."

Now, your Honors will remember that the only difference between claims 9, 10, and 11, which were held invalid, and the claims which were held to be valid, is that the claims which were held to be valid were limited in terms to the use of a fraction of 1% of oil, while the claims which were condemned as being too broad did not specify the amount of oil, except that it should be a "small quantity". We have called those the "small-quantity" claims,—those that were condemned; and the claims that were approved we have called the "fraction-of-one-per-cent" claims.

The first question is, How can counsel assist a Court in interpreting its own opinion? I certainly cannot assist your Honors by any amount of argument. I know of only one way in which I can assist you, and that is by refreshing your recollection as to the facts which were before you at the time the opinion was written. That is what I am going to do; and that is all I am going to do on this branch of the case.

Now, what did this Court have in mind when it said "It is clear from the record that approach was being made, slowly but more and more nearly to the result which was reached by the patentees of the process in suit"? What did this Court have in mind when it said "The investigations preceding were so informing that this final step was not a long one"?

Let me refresh your Honors' recollection as to the prior art which was before you in the Hyde case on that point. I have summarized it at page 11 of my brief. You will remember that the Elmore process, which was known as the 'bulk-oil' process, used some 100 to 300% of oil on the ore. Kirby used as little as 25% of oil on the ore.

[I may say that the figures which I am giving are the figures which were given by plaintiffs' witnesses and not those given by defendant's witnesses; because in some cases the defendant's witness made a lower estimate than did the plaintiffs' witnesses; but the figures which I am giving you are the figures which were given by the plaintiff's witnesses.]

I say Kirby used as little as 25% on the ore.

Haynes used as little as 11% on the ore.

Everson used as little as 5% on the ore.

The Froment patent used as little as 5% on the ore—the same as Everson.

Cattermole used as little as 4% on the mineral contents. Cattermole proportions were not given on the ore; they were given on the mineral contents of the ore; and he used as little as 4% on the mineral contents. Now, 4% on the mineral contents of the Broken Hill tailing, which was the ore to which this Cattermole process was applied by the plaintiffs in this case—4% on the mineral contents of that ore, Professor Chandler, plaintiffs' expert, tells us, equals 1.2% on the ore. So Cattermole proportions applied to the Broken Hill ore, as they were by the Minerals Separation, was only 1.2% on the ore.

The same proportions (that is, 4% on the mineral contents) applied to defendant's ores in this case, which carries 22% mineral contents, amounts to 0.88% on the ore. That is, practically speaking, 9/10 of one per cent.

When we come to the patent in suit we find that the proportions are as little as 2/100 of 1% on the ore. We find that the largest quantity that is mentioned in the patent anywhere is one-half of 1% on the ore. We find that the preferred quantity is one-tenth of 1% on the ore.

Mr. Justice Pitney: Do you understand it was intended to be specified that the percentage of oil was to be constant with different ores and different materials, or that the percentage of oil was to vary with the material? The specifications say that the oil is to have a certain affinity for the ore and the process is to be thus and so.

Mr. Bull: Your Honor, I appreciate that, and I will read you in one moment what my adversaries said on that point. They said that the largest amount which had ever been found useful in practice was two-tenths of 1% on the ore. I will read that. They said that of all the oils that had been used, and with all the ores that ever had been used up to that time, two-tenths of 1% was the largest quantity that had ever been found useful. I will refer to that later in my argument.

What, then, was the "final step" which this Court said was "not a long one"? I submit that it was a step from a large fraction of 1% to a very small fraction of 1%. In another art it might seem as if this was no step at all, but in this art very little things may be very big things measured in dollars and cents. It is in evidence here that in one of the Jackling group of mines, the Utah Copper Company, a reduction in oil from nine-tenths of 1% to one-tenth of 1% would effect a yearly saving in the cost of oil alone of three and a half million dollars. So in this art we must learn to respect little things.

What did this Court have in mind when it said "The patent must be confined to the results obtained by the use of oil within the proportions often described in the "testimony as 'critical proportions' "? What were the "critical proportions" often described in the testimony? May it please your Honors, every witness for the plaintiffs said that the critical proportions were somewhere in the neighborhood of one-tenth of 1% on the ore, and in practice had never been found to exceed two-tenths of 1%.

Counsel said in their brief before this Court in the Hyde case on that point this:

"It is the astonishing fact that, so far as the record here shows, with every ore the world over to which the process has been applied and with all the varying conditions of use, the largest quantity ever used has been four pounds to the long ton (that is, less than 2/10ths of 1%), and that the smallest quantity has been 9/10ths of a pound per long ton of ore (that is, less than 1/2 of 1/10th of 1%)."

Mr. Justice Clark: What are your reading from?

Mr. Bull: I am reading from page 14 of my brief.

Mr. Justice McKenna: That is an extract from the brief of counsel in the Hyde case?

Mr. Bull: Yes, your Honor.

The Chief Justice: Just read that extract over.

Mr. Bull: "It is the astonishing fact that, so far as the record shows, with every ore the world over to which the process has been applied and with all the varying conditions of use, the largest quantity ever used has been four pounds to the long ton (that is, less than 2/10ths of 1%), and that the smallest quantity has been 9/10ths of a pound per long ton of ore (that is, less than 1/2 of 1/10 of 1%)."

Now what were the "proportions that have been described in the testimony as the 'critical proportions' '? Counsel summarized the testimony of their witnesses on this point beginning on the very first page of their brief in this Court in the Hyde case in the following language. I am still reading from page 14 of my brief.

"The distinctive feature of the invention patented is the employment of air bubbles in co-action with a *minute and critical* amount of oil in a mixture of ground ore and water so as to produce upon the surface of the water a froth containing substantially all of the metallic particles which can be easily flowed off or removed. This process was never used before. This result was never obtained before. The process is dependent upon the use of oil in a *minute and critical* amount and thorough aeration. If *more* oil is used, you do not operate the process, and you do not get the result. So also if less oil is used the process is not operated and the result is not obtained."

Mr. Justice Pitney: They meant the kind of oil that they were dealing with, the oil that had a peculiar affinity for the ore.

Mr. Bull: I am coming to that. That is the second point in my argument. I shall answer fully what I know is in your Honor's mind. I am not trying to answer it now.

Mr. Justice Pitney: All right.

Mr. Bull (continued reading): "By using other and greater quantities of oil you operate a different process and you obtain wholly different results. That the *critical* amount of oil characterizing the process is a *minute* amount of oil (varying slightly with different ores and different oils) is merely a fortuitous circumstance. Nevertheless the process is dependent upon such *definite minute amount of oil.*"

And at page 10 of their brief they said:

"It is also known that the process is destroyed if the amount of oil is increased over the *minute* proportions characteristic of the process. This latter fact, namely, that the process is in each instance conditioned on the use of *definite and astonishingly minute* oil proportions (varying slightly with different ores and different oils), is one of the important facts that is clearly proved in the evidence in behalf both of complainants and of defendant which the Circuit Court of Appeals overlooked or disregarded."

Counsel in the Hyde case repeated those statements over and over again in their brief and in their oral argument: and they emphasized them in colloquy with the Court. I read from page 17 of my brief. Mr. Justice McReynolds asked Mr. Kenyon, who was then in argument:

"I would like to ask you when in this process of reducing oil your invention came into existence?

"Mr. Kenyon: At about one-half of 1% of oil.

"Mr. Justice McReynolds: Before you got to the one-half of 1% did you have any invention?

"Mr. Kenyon: We were passing from the region of Cattermole, which was a distinct——

"Mr. Justice McReynolds: I want to know when your invention came into existence?

Mr. Kenyon: This invention was not reached, I should say, from those figures, until about 0.5, that is, one-half of 1% of oil was reached.

"Mr. Justice McReynolds: At 1% you had no invention?

"Mr. Kenyon: No.

"Mr. Justice McReynolds: At one-half of 1% you did have invention?

"Mr. Kenyon: It began to come. Remote, but it began to come. At 0.3 of 1% the float vastly increased.

"Mr. Justice McReynolds: *When this float has more than one-half of 1% of oil it does not infringe?*

"Mr. Kenyon: *It does not infringe.*

"Mr. Justice Pitney: What have you to say in answer to what Mr. Scott said the other day to the effect that 1.8%, or perhaps more, of oil, would give the same result with increased agitation?

"Mr. Williams: Absolutely no.

"Mr. Kenyon: It would not.

"Mr. Justice Pitney: I understood him to say so yesterday, and I suppose there was something in the record to justify it.

"Mr. Kenyon: Nothing. That will be a part of my argument."

Mr. Justice Pitney: Can you refer me to the text? This refers to certain pages and also refers to a copy of the printed oral argument. What is that copy?

Mr. Kenyon: I think we have a copy here.

Mr. Williams: A copy of the printed oral arguments was sent to this Court after the argument in the Hyde case. Counsel joined in printing it. It was sent to this Court. I do not know whether it was treated as a filed document. I do not think it was. But we can supply your Honors with other copies.

Mr. Justice Pitney: I have an idea that this colloquy occurred in connection with experiments leading up to the discovery.

Mr. Bull: It did.

Plaintiffs' expert witnesses testified on this point as follows: Professor Chandler said that he understood "*a* fraction of 1%" referred to in the claims as being *the* fraction of 1% which is described in the specifications. The specifications contained this statement, and the only statement, as to quantity:

"To this is added a very small proportion of oleic acid, say from 0.02% to 0.5% on the weight of ore."

And he continues, "that is, from 1/50th of 1% up to 1/2 of 1%."

Professor Chandler said, after reading the claims, "What *this* fraction of 1% is, they do not mention." [That is, the claims do not state. They say *a* fraction of 1%, but they do not say *what* fraction of 1%.] He says, "What *this* fraction of 1% is, they do not mention. The only way in which I can interpret *this* fraction of 1% is by referring to other portions of the specification, where *this* fraction of 1% is expressed in figures; for example, at line 81 on page 1 of the specification is the following statement"—which statement I have just read.

In other words, he said that *the* fraction of 1% which is the subject of this patent is *that* fraction which is between 1/50th of 1% and 1/2 of 1%.

Mr. Ballantyne, the English expert for the plaintiffs, stated that he did not understand that *the fraction* of 1% of this patent was *all fractions* of 1%. He said 0.999% would not, in his opinion, be the fraction of 1% which is referred to in the patent in suit.

So when this Court said "the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony as critical proportions," we submit that it must be confined to the use of something in the neighborhood of one-tenth or two-tenths of 1% of oil, and not above one-half of 1%, which is the largest quantity mentioned in the patent, and which was a larger quantity than the plaintiffs said had ever been found useful in the process.

That is precisely what the Court of Appeals in this case has held, and that is all the Court of Appeals in this case has held.

I shall take up the contention that petroleum oils are not among the "oils or oily substances" of the patent in suit.

The defendant has used different mixtures, but the mixture which has been taken as typical by both sides is a mixture of three parts petroleum oils—that is, fuel-oil and kerosene, three parts.

Mr. Justice Clark: Please repeat that.

Mr. Bull: I say the mixture which has been taken as typical by both sides is three parts of petroleum (partly fuel-oil and partly kerosene) and one part of vegetable oil.

Now, the plaintiffs contend that petroleums are not among the "oils or oily substances" of the patent in suit, and that the petroleum should be subtracted from the amount of oil which we use in order to determine what is the actual amount of what they call 'effective' oil used by the defendant.

Your Honors doubtless understand that crude petroleum, as it comes from the wells, is separated by what they call fractional distillation into its several parts. The lightest is known as 'gasolene', the next heavier is known as 'kerosene', and the next heavier is known as fuel-oil', and the next heavier is known as 'lubricating oil', and what remains is known as 'residuum. These different petroleums differ from each other only in their boiling-points. They are separated simply by fractional distillation. Gasolene is the lightest and residuum is the heaviest of the series. And the question is, are these petroleums among the "oils or oily substances" of this patent.

This is a pure question of fact, may it please your Honors. It is a question of fact on which the District Court in this case, as well as the Court of Appeals in this case, has found in favor of the defendant. In other words, neither of the courts below has found that petroleum oils are not among the "oils" of this patent. We have never asked any court to find that anything in our mixture which is inert and inoperative in the process is a part of the oil of the patent.

In the first place, we take up the specifications of the patent in suit. They describe the "oils" which are to be used in the process in these words:

"Oils, fatty acids or other substances which have a *"preferential affinity for metalliferous matter."*

And when we come to the claims, we find that they all define the "oils" to be used in these words:

"An oily liquid having a *preferential affinity for metalliferous matter."*

So, the first question is, Do petroleum oils have a *preferential affinity for metalliferous matter*, which is the requirement of the specifications and of the claims?

May it please your Honors, even my adversaries admit that petroleum oils have a preferential affinity for metalliferous matter. As a matter of fact, they have a very high preferential affinity, even a higher preferential affinity for metalliferous matter than does oleic acid, or pine-oil, or other vegetable oils. It is admitted, therefore, that petroleum oils fall literally within the terms, and literally within the four corners of the "oils" of the patent in suit.

In the next place, at the very birth of this invention, on March 5, 1905, the patentees wrote a report of the invention to the Minerals Separation, describing the invention. It is the first written description of the invention which appeared, written by the patentees, and I quote from it at the bottom of page 65 of my brief. After describing experiments with oleic acid, they say this:

"We may here conveniently note that other oils besides oleic acid may be employed in this modified recovery process, but so far as Broken Hill is concerned oleic acid gives by far the best results. Petroleum residuum"——

The Chief Justice: What term is that? Petroleum what?

Mr. Bull: Petroleum residuum. That is the heaviest of the petroleums.

"—added as emulsion, paraffine oil alone"——

Paraffine oil is the English name for kerosene, so we can read it "kerosene alone."

"Petroleum residuum added as emulsion, paraffine oil alone, R_3P_1 and R_1P_3"——

Those formulæ mean, as explained in the testimony, a mixture of 3 parts of residuum and 1 part of kerosene, and a mixture of one part residuum and three parts kerosene

"—have also been used"——

Mr. Williams: As emulsions. You omitted that.

Mr. Bull: Well, they are mixtures.

Mr. Williams: As emulsions.

Mr. Bull: Well, mixtures, or emulsions, or anything you please, but they are both petroleum.

"—have also been used, and all give small proportions of float, but do not act nearly so vigorously or efficiently on Broken Hill ores as plain oleic acid."

Now, the patentees in this first description, the very first description, of the invention, say that petroleum may be used instead of oleic acid, but they say on Broken Hill ores petroleums do not give as much froth or as good results as oleic acid.

As a matter of fact, very shortly after that description was written, Mr. Higgins, pursuing his investigations for the Minerals Separation tried gasolene, which, in England, is known as 'petrol'; and he found that that gave, on Broken Hill ores, as good a recovery as oleic acid. That is admitted.

Mr. Justice Clark: You say that is admitted?

Mr. Bull: Yes, your Honor. It is his, Mr. Higgins' testimony. I have it in my brief.

In the next place, the British patent in its complete specification—the British patent which corresponds with the patent here in suit—wherever it mentions oleic acid invariably includes "petrol" as its equivalent. The phrase is always "oleic acid, petrol, etc."

The fact is, these British complete specifications were written after Mr. Higgins had tried gasolene and found that it worked on Broken Hill ores. That complete specification is almost word-for-word like the patent here in suit, except that wherever it mentions oleic acid it also mentions "petrol"—a petroleum.

In the next place, prior-art patents which were before your Honors in the Hyde case, almost every one of them mention the use of petroleums in this ore-recovery process. I have not time to refer to them, but you will find them each referred to in my brief, and the particular kind of petroleum product which is mentioned in each of them.

In the next place, plaintiffs, in the Hyde case, put their expert, Professor Chandler, on the stand to state in his direct examination, affirmatively, that petroleums were among the "oils or oily substances" of the patent in suit.

I may say (I am practically only reading my headnotes, because my time is very short) for every statement I have made, or will make, you will find a reference, by chapter and verse, to the part of the record where it is supported, in my brief.

In the next place, the plaintiffs' engineers in the Hyde case stated over and over again that they had used petroleum alone, and in mixtures, in the commercial practice of this invention, when using only about one-tenth of 1% on the ore. For example, their engineer Higgins said that he has successfully used not only "petrol" but also, quoting him, "Certain portions of "the distillate of crude petroleum, such as Cosmos oil" (and explained that Cosmos oil was petroleum lubricating oil).

Engineer Chapman said that at Broken Hill they use a mixture of oleic acid and Karsam soap, and he added that Karsam soap was a petroleum soap.

The same witness said that in the Braden mine in Chile they used a mixture of three parts Texas fuel-oil and one part American wood-tar oil. That is three parts petroleum and one part vegetable oil—precisely the mixture which the defendant is using at the present time.

All this testimony was before your Honors in the Hyde case. In this case the plaintiffs' witnesses amplify this very greatly. Their engineer Greninger says that he has used various mineral oils, fuel oils, and so forth. Fuel-oil, as you will remember, is a petroleum. Also that at the Inspiration plant they use a mixture of wood-tar oil and certain "mineral oils", which is only another name for petroleum. He also says that at the Britannia mine they use a mixture composed of three parts petroleum and one part wood-tar oil, which is precisely the mixture which the defendant is using in this case.

Plaintiffs' engineer Chapman says, in this case, that at the Consolidated Arizona mill they use a mixture of one-half stove-oil, which is a petroleum, and one-half turpentine; also at the Anaconda mine they use both stove-oil and fuel-oil, both of which are petroleums.

Plaintiffs' witness Wiggin says as a result of many tests at the Anaconda mine they found that the best oil to be used was a mixture of kerosene, sludge acid, wood-creosote, and stove-oil. Kerosene and stove-oil are petroleum.

Plaintiffs' witness Atwater says that at the Basin mill he used a mixture of five oils, one of which was kerosene.

The simple fact is that the use of mixtures containing petroleum is practically universal the world over today by the licensees of the plaintiffs, by those who are only using in the neighborhood of one-tenth of 1% on the ore. I have not referred to the testimony——

Mr. Justice Pitney: You say that the use of petroleum mixtures is universal among those who are using one-tenth of 1%?

Mr. Bull: Yes, your Honor. Every example which I have given here is an example where they were using in the neighborhood of one-tenth of 1% on the ore.

Mr. Justice Pitney: How much are you actually using?

Mr. Bull: We are using always more than one-half of 1%, and a large portion of the time more than 1%.

Mr. Justice Pitney: In using more than 1% of the mixture——

Mr. Bull: Yes, your Honor.

Mr. Justice Pitney: —do you get the same process as described in the patent? I mean air-flotation. I mean froth-flotation, as distinguished from oil-flotation.

Mr. Bull: Your Honor, you are asking me now a question which calls for legal interpretation. You ask me if we are using substantially the same process. Your Honor will recall that in the Hyde case we said that in using more than 1% of oil the process and the results were substantially the same as when you use a small fraction of 1% of oil. Your Honor remembers that that was our contention, and that was the contention which was sustained by the Court of Appeals in the Hyde case; and therefore the Court of Appeals held that the patent was invalid. Now, in the Hyde case my adversaries said. No: when you use more than 1%, or more than the "critical quantity", you are not practising the same process and you do not get the same result, because they said by the use of the critical quantity you get a *dry* froth, which carries the *maximum* amount of values.

They said, if you use a greater quantity of oil than the "critical quantity" you get an *oily froth*, which carries a *less quantity* of values; and they said, that is not *our* froth. And that is the contention which your Honors, as I understand it, adopted. They said, These prior-art quantities do not give *our* froth and do not give *our* result.

Mr. Justice Pitney: Is it your present suggestion that they were mistaken about that?

Mr. Bull: No, your Honor. I am saying this: I am saying that in precisely the same sense we are not using *their* process and we are not getting *their* results, because it is admitted by everyone that our froth is more *oily*, as it must obviously be when we use ten times as much oil. It is not only admitted, but it is affirmed, that our froth does not carry the *maximum* ore-values, for my friends put a witness on the stand to testify from our records that our results, our recoveries, were not as high when using this large amount of oil. They figured that we were losing more than a million dollars a year in reduced recovery by using this larger amount of oil. So when you ask me if we are practising the "same process", you see I can only answer by giving a legal definition as to what the "same process" is.

Mr. Justice Pitney: You say practically you are practising the same process aside from percentage?

Mr. Bull: I say we are practising the prior-art process.

Mr. Justice Pitney: You are in a difficult position.

Mr. Bull: We are infringing if the prior-art anticipates. If the prior-art does not anticipate, we are not infringing.

Now, I wish to say that the defendant here is one of a group of mines which are commonly known as the Jackling mines, and we have testimony from all those various mines, and at all of them, before the decision of this Court was handed down in the Hyde case, they were using this same mixture of oil (petroleum and vegetable oils) that they are using today. After your Honors handed down your decision in that case they all changed their practice and increased the amount of oil above one-half of 1% (the largest amount mentioned in the patent) and, much of the time, above 1%.

Mr. Justice McReynolds: Are the proportions just the same as they were?

Mr. Bull: They are in some cases, but not in others. The proportion we are using now, as I pointed out, is used by two of the plaintiffs' licensees, where they are using less than one-tenths of 1%—that is, three parts of petroleum oil and one part vegetable oil.

Mr. Justice McReynolds: The proportions that you use now are the same as they were when suit was brought for infringement?

Mr. Bull: As I stated before, we have used various mixtures. The one which I have taken here is the one which has been accepted by both sides as typical, because we had to talk about something, and we have taken that one; but, as your Honor will see from the record, we have used all sorts of proportions.

Now I wish to take up the question of the alleged disclaimer.

As your Honors know, at common law a patent containing one bad claim was bad in whole. It was totally void. That is the law in England today. That was the law in this country down to 1837. In that year Congress passed the disclaimer sections of the statute, which were designed to mitigate the hardship of that situation in a case in which the only defect of a patent was that it contains an overclaim; that is to say, that it claimed too much. And those sections provide that if a patent contains an overclaim, and merely an overclaim, the patentee may file in the Patent Office a disclaimer, and that he may maintain suit on the patent while it is in that defective condition, provided that he does not "unreasonably neglect or delay to enter his disclaimer." The language of the section is as follows:

"Sec. 4917. Whenever, through inadvertence, accident or mistake, and without any fraudulent or deceptive intention, a patentee has claimed more than that of which he was the original or first inventor or discoverer, his patent shall be valid for all that part which is truly and justly his own, provided the same is a material or substantial part of the thing patented; and any such patentee, his heirs or assigns, whether of the whole or any sectional interest therein, may, on payment of the fee required by law, make disclaimer of such parts of the thing patented as he shall not choose to claim or to hold by virtue of the patent or assignment, stating therein the extent of his interest in such patent. Such disclaimer shall be in writing," and so forth.

Section 4922 reads:

"Whenever, through inadvertence, accident or mistake, and without any wilful default, or intent to defraud or mislead the public, a patentee has, in his specification, claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which he was not the original and first inventor or discoverer, every such patentee, his executors, administrators and assigns, whether of the whole or any sectional interest in the patent, may maintain a suit at law or in equity, for the infringement of any part thereof, which was *bona fide* his own, if it is a material and substantial part of the thing patented, and definitely distinguishable from the parts claimed without right, notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer. But in every such case in which a judgment or decree shall be rendered for the plaintiff, no costs shall be recovered unless the proper disclaimer has been entered at the Patent Office before the commencement of the suit. But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer."

What are the "benefits" of that section? The "benefits" of that section, may it please the Court, are that a patentee can maintain a suit on a patent while it is in a defective condition, something that he could not do before that section was enacted, and the condition of enjoying those "benefits" is that the patentee must not unreasonably neglect or delay to enter his disclaimer. If he unreasonably neglects or delays to enter the disclaimer then he cannot maintain a suit on his patent.

As soon as your Honors' decision in the Hyde case was handed down, in which you pointed out that three of the claims were too broad, that patent began to expire. It could only be saved by a prompt surgical operation; it could only be saved by either cutting out of the patent altogether those small quantity claims, which were declared to be invalid, or by trimming those claims down so that they were limited to the results obtained by the use of a fraction of 1% of oil. Now, neither of these things was done. A paper called a disclaimer was promptly filed, but our contention is that that paper was not a disclaimer in fact or in law. Our contention is that that paper did not cut out anything at all. Our contention is that that paper, masquerading as a disclaimer, as a matter of fact was intended to and actually did broaden the condemned claims. If we are right the plaintiffs have no right at the present time to maintain a suit on their patent.

Now I shall read to your Honors the material part of the alleged disclaimer, which you will find quoted at the bottom of page 101 of my brief. The material part of the disclaimer reads as follows:

"Your petitioner does hereby disclaim from claims 9, 10 and 11 of said letters patent No. 835,120, any process of concentrating powdered ores excepting where the "*results obtained are the results obtained* by the use of oil in a quantity amounting to a fraction of one per cent on the ore."

Your Honors will observe there, at once, the curious repetition of the words "results obtained." What your Honors said in your opinion was that these claims must be confined to the results obtained by the use of a critical amount of oil. What this disclaimer says is that these claims are limited to a process in which the "results obtained are the results obtained" by the use of oil in a quantity amounting to a fraction of 1%. In other words, these claims are now for a process in which the results obtained are *like those obtained* by using a fraction of 1% on the ore. These claims now are claims avowedly for a result. The "small quantity" of these claims is now any quantity, however large, provided the results obtained are *like those* obtained by using the small critical quantities. In other words, the claims have now been changed to claims for a result, and broadened, because the "small quantity" of these claims now is any quantity, however large, which will produce the desired results—which will do the work. And that is not only the effect of the disclaimer, but counsel for plaintiffs have told the Court it was the purpose of the disclaimer. I shall read from page 102 of my brief. This was a colloquy between Mr. Kenyon and the district judge. The Court said:

"The patent here in suit has been rather narrowly construed?

"MR. KENYON: On the contrary I think the Supreme Court has construed this patent broadly as for the process if and whenever the results obtained are those that are obtained when you effectively used this small quantity of oil."

And I read from page 93 of his brief before that court, in which counsel said that these claims, as changed by disclaimer, read as follows: He is paraphrasing the claims as they now read, as amended by disclaimer. He says, for example, claim 9 reads:

"The process of concentrating powdered ores which consists in separating the mineral from the gangue by coating the mineral with oil in water containing a small quantity of oil, agitating the mixture to form a froth, and separating the froth, when the results obtained are *substantially those that are obtained by the same procedure when the oil effectively used is a fraction of one per cent on the ore.*"

He adds, "That is the legal effect of that disclaimer."

That will be found at pages 103 and 104 of my brief.

In his brief in this Court plaintiffs' counsel says, and I am quoting now from page 105 of my brief.

THE CHIEF JUSTICE: What page?

MR. BULL: Page 105 of my brief. Having stated that Judge Bourquin regarded the opinion of this Court as a narrowing opinion, he says in this Court now:

"Petitioners do not so interpret the decision of this Court and respectfully present their interpretation, viz., that this Court, although having no evidence before it that the process could be worked with one per cent or more of any oil, nevertheless, in confining the patent and thereby limiting its scope, did *not* confine it to the use of a fraction of one per cent of oil, but to a *process identifiable by its results*, wherein the 'results obtained' were the new results first obtained by the process of the patent in suit."

In other words, these claims have been changed and expanded by disclaimer. There is nothing better settled in law than that anything which does not limit a claim is not a disclaimer in law or in fact; it is a nullity; and we submit that no legal disclaimer has been filed up to the present time. We submit that the paper that has been filed in the name of a disclaimer is not a disclaimer in fact or in law, but is an attempt to broaden and change the claims of the patent. That is a function which a disclaimer cannot legally perform; and if no legal disclaimer has yet been filed, the plaintiff has no right to maintain this suit.

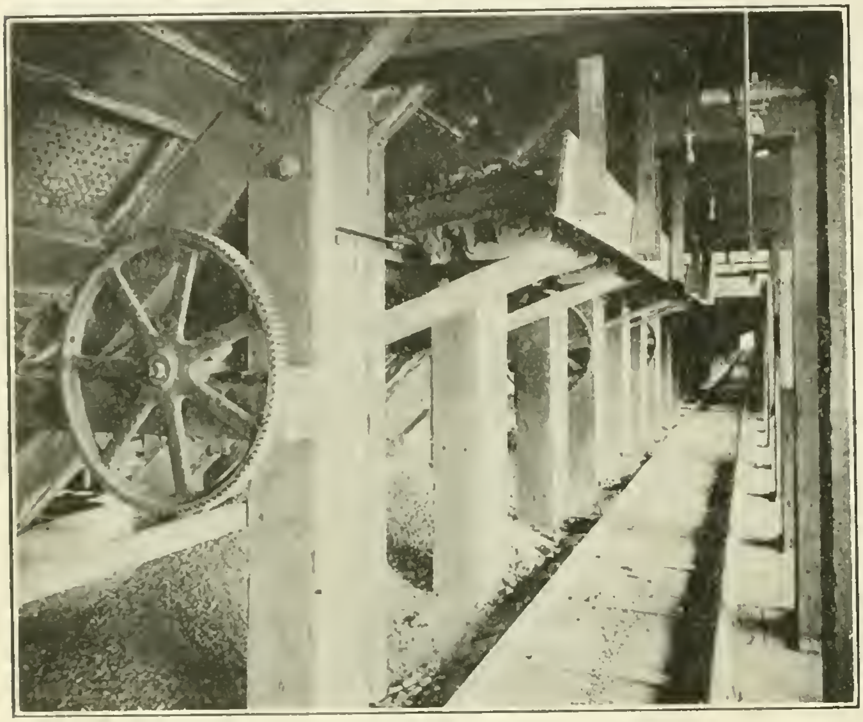
We submit that plaintiffs have not honorably complied with the conditions which were imposed upon them by your Honors' decision in the Hyde case, but have, by shifty practices, avoided complying with those conditions. They have used the exact words of your Honors' decision but, by a repetition of them, they have put an entirely different meaning upon them.

We submit that it is important, it is extremely important, that this Court at this time should lay down the rules as to what a patentee may, or may not, do under the guise of disclaimer.

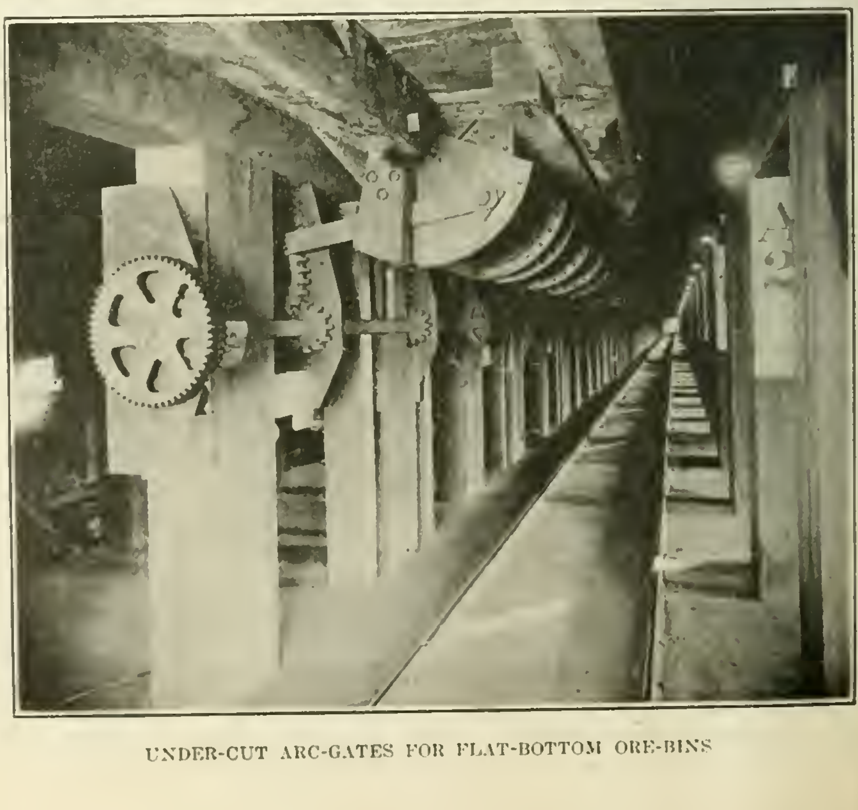
Mechanical Charging of Silver-Lead Blast-Furnaces

By L. D. ANDERSON

*At the Midvale, Utah, smelter of the United States Smelting & Refining Co. there is in use a system of making-up blast-furnace charges that is interesting by showing how largely hand labor can be eliminated by the employment of mechanical and electrical devices. The charges for silver-lead blast-furnaces are carefully proportioned according to the chemical composition of the various ores and fluxes entering into their make-up. The ordinary practice is to weigh the ingredients in hand-buggies, pull these up to and carefully distribute their contents in large charge-cars, which are run over the furnaces into which the proportioned charges are then dropped. This scheme worked well as long as operations were on a small scale, but as they increased in magnitude the bins required became extensive, necessitating long hauls for the buggies. The result was the development of a formidable crew of charge-wheelers, whose direction and management became a serious problem. Errors on their part were not infrequent, causing excessive metallurgical losses.



BELT-FEEDER FOR HOPPER-BOTTOM ORE-BINS



UNDER-CUT ARC-GATES FOR FLAT-BOTTOM ORE-BINS

To overcome the difficulties constantly encountered, it was decided at Midvale to change the system completely. This was done by substituting for the charge-wheelers, electrically-driven gathering-cars, which run under two long rows of bins, stopping at designated points and drawing out proper quantities of the required materials at the respective points. The hoppers of these cars are suspended on scale-beams, whose leverage systems end in a pointer immediately in front of the operator. Just before this pointer is a scale beam-box supplied with a sufficient number of beams to enable the operator to make settings for each and every ingredient for the charges.

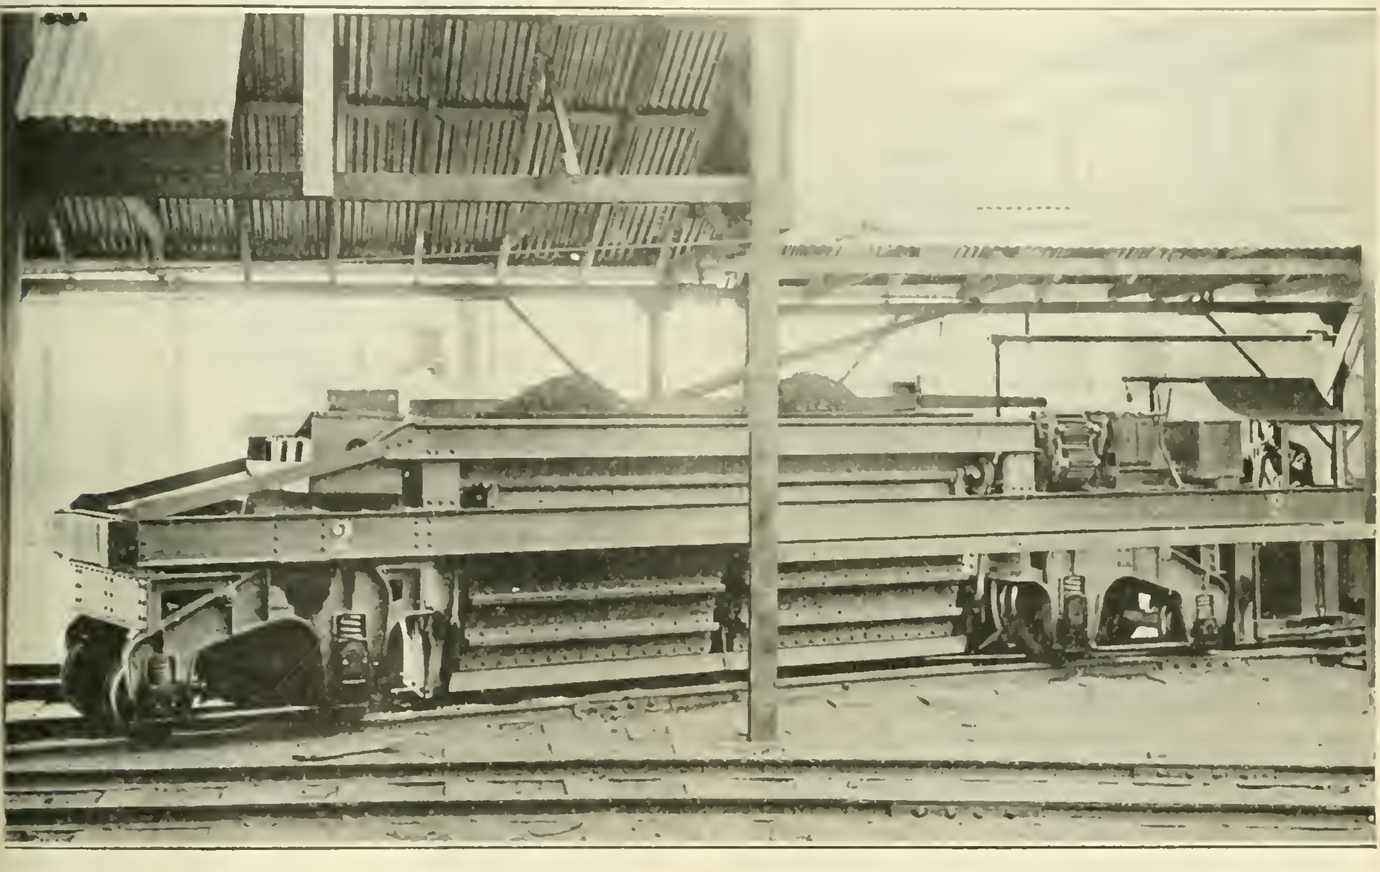
Ordinary bin-gates are out of the question when accurate weighing is necessary, so resort was made to electrically-operated mechanical gates or feeders. The necessity of utilizing an existing heavy bin construction made it compulsory to use two different types, an under-cut arc-gate for the row of flat-

---

*Abstract from Monthly Journal of Utah Society of Engineers, Jan. 1919.

bottom bins, and a belt feeder for the row of hopper bottom bins. Both types are operated in the same manner, the power being a 7½ hp. motor on the scale car. By means of a swinging gear on the car, this motor is put in mesh with the main gear driving each set of gates. This swinging-gear is thrown into mesh by simply pressing down a foot-treadle on the car. The belt-feeders move through the simple rotation of the large pulley at the rear, while the balanced arc-gates are actuated by a crank and connecting rod mechanism.

For accurate weighing, the belt-feeders are found at the start to be more sensitive than the arc gates; on the other hand, after a little skill has been acquired, a good operator can do about as well with either type. The under-cut arc-gate has one advantage in that it is seldom troubled by a preponderance of either coarse or fine material. The common bin-gate, wherein closing is effected from above, often catches on a large lump, permitting fine material to slide by. The under-cut arc-gate entirely overcomes this difficulty, getting a quick sharp cut-off. For the belt-feeders, heavy canvas belts, 36 in. wide, are used. Canvas has been found to have some advantages over the metal slat-type of belt or apron-feeders. It is considerably cheaper, and it does not have the tendency to jamb and stick, which sometimes happens when slats are bent by the shock of ore dumped upon them. The belts generally last from six to twelve months, according to the character of material handled. Some belts have given service several times as long as that.



ELECTRICALLY-DRIVEN GATHERING CAR WITH WEIGHING HOPPERS

Various metallurgical considerations had to be kept in mind in designing the several details, but space is too limited to discuss them here. It might be stated that the installation of the equipment thus briefly described, built by the Brown Hoisting Machinery Co., and patented by the Smelting company, has effected a saving of from 55 to 65 men formerly required to charge the blast-furnaces.

The smelter of the U. S. S. R. & M. Co. at Midvale, Utah, now contains seven blast furnaces, one being added during 1918 to meet the large supply of ore.

THE WEST END CONSOLIDATED mill at Tonopah during 1918 treated 66,518 tons of company and custom ore averaging $24.06 per ton. The gold content was 14,316 oz. and silver content 1,334,010 oz., of which 94.30 and 91.95%, respectively, was extracted. The actual cost of treatment was $2.94 per ton of ore, equal to 14.5 cents per ounce of bullion; and the additional cost of sampling and marketing was 35.4 cents per ton or 1.8 cents per ounce. The consumption of sodium cyanide was 0.131 lb. per fine ounce, and that of zinc 0.053 lb. Two crucible melting-furnaces were replaced by a No. 3 double-chamber Rockwell furnace, a No. 3 Root blower, and a briquetting-machine, at a cost of $3303. This new equipment reduced 1,240,177 oz. of bullion, costing, including briquetting of the precipitate, $0.0035 per ounce. The saving over the cost in 1917 was a total of $1596, so that in about one year's operation the furnace saved nearly 50% of its first cost.

The Efficient Compression of Air

By CHARLES A. HIRSCHBERG

*Economical and efficient operation of air-compressors demands regular inspection. The compressor as a whole should be inspected at least once a month, making necessary adjustments, such as taking-up of packing-glands and replacement of worn parts. Air-valves should be examined and should show an oily surface free from carbon. Ports and passages also should be examined for carbon or other obstructions. Carbon deposit on valves prevents their seating properly, causes leakage and results in reduced compressor-capacity and low efficiency. Obstructions in air-passages reduce their area and cause loss in friction. A carbon deposit, in combination with high temperature, due to improper cylinder cooling, sticking of valves, or insufficient lubrication, may result in explosions, if allowed to persist. Remove any carbon deposited.

The use of packing is often misunderstood. Drawing up too tightly will cause heating, and scoring of the piston-rod. This means higher temperatures and increased mechanical friction, with transmitting of increased temperature to the air cylinder, causing trouble from moisture, lowering the air density, and thereby reducing the output.

In placing the packing in a stuffing-box, put the rings in so that the joints of the several rings stagger. Fill the box without crowding, and with new packing force in slightly with the gland until the compressor warms up: then draw up just enough to prevent blowing. Crowding the packing will squeeze-out the lubricant it contains, causing the packing to become hard and unyielding. If upon examination packing is found to be hard, it may be revived by removing, loosening up, and working in a mixture of graphite and grease. Asbestos-sheet packing is generally used between cylinder-heads and cylinders. If for any reason it becomes necessary to remove a head, care should be exercised not to injure this head-gasket. If necessary to replace it, be sure to use material of the same thickness as the original, so as to maintain the clearance established by the builder.

Do not have the air-intake open to the engine-room. Carry it outdoors and extend upward a sufficient height, with hood and screen, to prevent foreign substances from being drawn-in and to ensure cool intake air. Fig. 1 shows an ideal method of handling the air-intake. Take the air into the compressor as cool as possible is the rule without any exception. Cooling the intake air is a direct saving of power by reducing the volume to be compressed. The capacity of the air to hold moisture falls off rapidly as its temperature is reduced.

Pipe-lines should be of ample size, as small transmission-lines mean excessive loss of pressure due to friction. Large pipe-lines are especially desirable where the pipes are long or the supply has to meet the demands of a great many devices. Reduced pressure due to friction means inefficient operation of tools. The accompanying chart, Fig. 2, covering loss in pressure due to friction in pipe-lines, will serve to indicate the need for having the pipe-line of ample size. Take, for example, the following case:

The loss in pressure in transmitting 50 cu. ft. of free air per minute at 100 lb. pressure through 1000 ft. of 1-in. pipe is 11.89 lb., and only 0.27 lb. in transmitting the same volume of air the same distance through a 2-in. pipe.

Air-lines should receive monthly inspection for leaks. Assuming that 1 cu. ft. of air per minute at 100 lb. pressure costs $5 per year, this cost being computed from an estimated charge for electricity at 1c. per kw-hr., interest and depreciation at 10%, and a year as 300 eight-hour days, the following demonstrates the economy of regular pipe-line inspections:

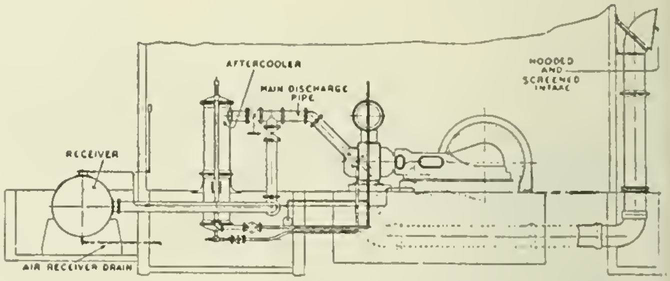


FIG. 1. PROPER ARRANGEMENT OF AIR-INTAKE AND PIPING

Amount of Leak in Cubic Feet

Diameter of hole, inches	Free air per minute	Cost per year
1/16	6.45	$32
1/32	1.61	8
1/64	0.40	2

Further calculations of possible loss through leaks may be quickly made by applying the above constant to the various discharge volumes shown in Fig. 3.

It is always advisable to provide numerous outlets in the transmission-line. This will have future reconstruction, and make it possible to use comparatively shorter lengths of hose. Where a number of supply-lines radiate from the main line, it is well to provide a gate-valve for cutting out any of these lines when they are to be idle for any considerable period of time.

Several methods are used of detecting air leaks: By the use of a lighted candle at all joints and connections, by swabbing soapy water around the joints, or by fol-

lowing the practice of one Illinois manufacturer, who, at regular intervals, put essence of peppermint into the air system and then has all the pipes inspected. Leaks are revealed by the odor.

FIG. 2. LOSS OF AIR-PRESSURE IN PIPE TRANSMISSION

Pipe-lines may be tested for loss of pressure due to friction in transmission or to leakage by placing an air-gauge at the point of use of the air, and comparing its reading with that of the gauge on the air-receiver. The remedies are increasing the size of the air-line and eliminating of leaks.

All air contains moisture. When compressed, the moisture becomes more evident, as in the compressed state there is more water in the air than it can contain. The excess moisture is deposited almost immediately as the air travels to the receiver; part of it travels with the air through the transmission-lines, being gradually deposited and draining to low spots in the pipes, reducing the available area. Some of the moisture will find its way into the ports and exhaust-passages of the machinery using the air, resulting in interference with proper operation by freezing at exhaust ports as the air expands to atmosphere.

One of the most effective and cheapest methods for the elimination of moisture from pipe-lines is the placing of suitable traps at intervals in the transmission-line, into which the condensed moisture will precipitate and can be conveniently withdrawn. A simple moisture trap, Fig. 4, consists of an enlargement of the air line. It is provided with baffles and blow-off, the former having holes or slots drilled in the bottom so that moisture can work through to the blow-off pipe. By reason of the pressure always present in the separator the water can be taken from the top. This trap may be made of wrought or cast-iron pipe, with flanged or screwed heads. A good proportion is separator diameter 3 times the air-line diameter and 4 to 6 ft. long. Another effective design is shown in Fig. 5. It consists of a long-sweep tee, three times the diameter of the pipe, with a pocket below to catch the condensed moisture. Both of these separators may be made locally from standard pipe-fittings; also, there are a number of standard-built moisture-traps that may be purchased from various manufacturers. Moisture-traps should be placed at low points in the air-line.

Re-heating the air is a simple process, and serves the double purpose of eliminating annoyance due to freezing as a result of the moisture that the air may contain, and at the some time increasing the air volume.

When the warm compressed air leaves the compressor, and passes through the receiver and the transmission-lines to the point of use, the temperature of the air is considerably reduced. This represents a loss in volume. If the air were used immediately adjacent to the point of production, this loss would not be experienced; but the latter condition seldom, if ever, prevails.

Re-heating the compressed air, at the point where it is to be utilized, a temperature of 250°F., which is usual, results in expanding it in volume from 30 to 35%, at a cost of about ⅙ of the heat-units required to produce the same volume by compression. This approximation is based on the use of effective form of re-heater, and the use of the air in the cylinder of the engine immediately after passing from the re-heater. In using the re-heater, therefore, it should be placed as closely as possible to the point of use of the air, to prevent loss from radiation of heat after the re-heating process. The re-heater may consist of a cast-iron chamber containing a coil of pipe exposed to a fire, or a current of hot gas or steam. Fig.

6 shows a cross-section view of one standard type of re-heater, which requires no explanation.

Two tables given in Fig. 7 show the horse-power required for compressing air in single-stage and two-stage compressors at various gauge-pressures. All the conditions of the calculations given are explained in the headings.

FIG. 3. DISCHARGE OF AIR FROM ROUND HOLE TO ATMOSPHERE.

Mechanical efficiency of an air-compressor is represented by the ratio of the indicated air horse-power to the indicated steam horse-power in the case of a steam-driven machine, and to the brake horse-power in the case of a power-driven machine. The difference between the two represents excess power required to overcome frictional resistance of the machine, which is largely dependent on the design, workmanship, and supervision received when in operation. Mechanical efficiency of a well-designed compressor ranges between 90 and 95%.

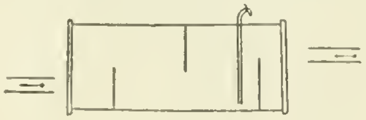

FIG. 4

Let us assume a power-driven air-compressor of the following size and displacement, and determine its mechanical efficiency:

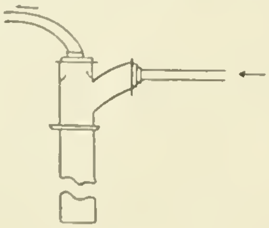

FIG. 5

Diameter of low-pressure cylinder, 16 in.; diameter of high-pressure cylinder, 10 in.; stroke, 14 in.; r.p.m., 165; discharge-pressure, gauge, 100 lb.; piston displacement, cu. ft. per min., 534. From brake-test it was found that the brake horse-power is 93. The air indicator-cards give an indicated horse-power of 83.6. Therefore 83.6 ÷ 93 = 92% mechanical efficiency.

As stated above, loss in mechanical efficiency is determined by frictional resistance. This is a factor that can be largely controlled by the supervising engineer. In general, it is desirable that attention be given to the lubrication system to ensure that all rubbing-parts are sufficiently lubricated at the following points: Bearings, cross-heads, stuffing-boxes, and cylinders, as they constitute the chief sources of loss due to friction. Bearings should be drawn up only enough to ensure smooth operation, without undue pressure. Instructions covering the packing of stuffing-boxes have already been given. Cross-head guides must be free enough to permit the cross-head

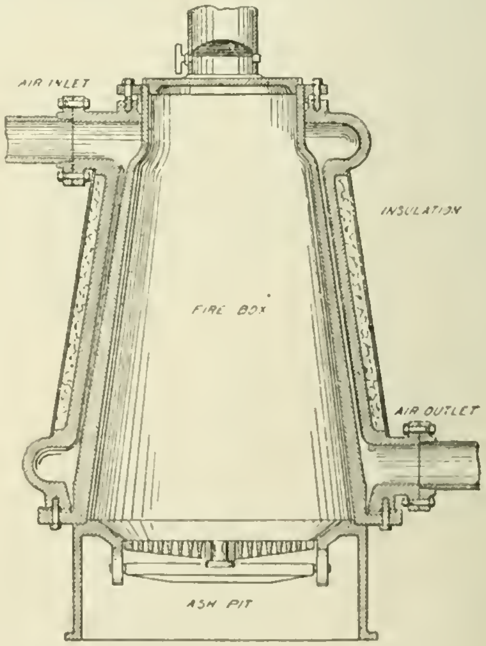

FIG. 6. STANDARD AIR RE-HEATER

to operate without undue pressure, and yet work without knocking.

Different measurements necessary for the calculation of efficiencies are given on the diagrams shown in Fig. 8 and 9. Following are stated the ratios of these measurements resulting in the respective efficiencies and performance measurements of an electrically-driven and a steam-driven compressor.

All compression efficiencies should be subject to correction to perfect inter-cooling, if the specified amount of water at specified temperature is not available.

The theory of compound or stage compression is very readily understood. It is generally conceded that compound or stage compression should be employed (*a*) with small capacity machines when pressures range over 125 lb., (*b*) with large capacity machines when pressures range above 70 lb. The heat of compression increases with the pressure, therefore, the higher the pressure, the more difficult it is to reduce the temperature of the air to a point where efficient compression conditions and proper air-cylinder lubrication obtain. For instance, in compressing air to 100 lb. terminal gauge-pressure in a single cylinder, the final temperature would be about 185 F. Some of this heat would be absorbed by the cylinder-walls and water-jackets, but the final temperature would remain too high to ensure efficient compression conditions and proper lubrication.

$$\frac{\text{Length l p intake-line}}{\text{Length indicates dagram}} = \text{indicated volumetric efficiency}$$

$$\frac{\text{Actual volumetric efficiency}}{\text{Indicated-volumetric efficiency}} = \text{air i hp per 100 cu. ft delivered per min.}$$

$$\frac{\text{Isothermal factor}}{\text{Air i hp per 100 cu ft delivered per min}} = \text{isothermal compression efficiency.}$$

$$\frac{\text{Isothermal factor}}{\text{I hp steam cylinder per 100 cu ft per min}} = \text{overall isothermal compression efficiency}$$

$$\frac{\text{Pounds steam per hour}}{\text{I hp steam-cylinder}} = \text{steam consumption per I hp hour}$$

$$\frac{\text{Pounds steam per min.} \times 1000}{\text{Cu ft free air delivered per min.}} = \text{lb. steam per 1000 cu. ft. air delivered.}$$

In Fig. 10 is shown a theoretical combined indicator-diagram from a two-stage compressor. It is assumed that the compression follows the adiabatic curve in both cylinders, with perfect inter-cooling between. $AB =$ volume of low-pressure cylinder; $CD =$ volume of high-pressure cylinder, both drawn to the same scale. $ACF =$ pressure to some designated scale; BEK (adiabatic curve) = relation between pressure and volume for any piston position, with no inter-cooling and no radiation through the cylinder-walls. In this curve the product $PV^{1.41}$ is constant (1.41 is the ratio between the specific heat of air at constant pressure and constant volume), where $P =$ pressure and $V =$ volume. BDH (isothermal curve) = relation between pressure and volume, provided the temperature of the air under compression could be kept constant so that the product PV would also be constant. Air taken into the low-pressure cylinder at zero gauge-pressure, is compressed along the adiabatic curve BE until at E it attains a pressure of 26.3 lb., equal to that of the inter-cooler, allowing the discharge-valves to open and the air to pass into the cooler. In the inter-cooler, the volume of a definite weight of the air is reduced from CE to CD, so that the volume entering the high-pressure cylinder is less to the extent of *DE,* which is the same scale as *CD* and *AB.* This means that the given weight of air represented by the volume *CE* at a gauge-pressure of 26.3 lb., when cooled to the same temperature at which it was originally taken into the low-pressure air-cylinder, will be reduced in volume to *CD* provided the pressure of 26.3 lb. remains constant.

Air taken into the high-pressure air-cylinder at 26.3 lb. is compressed along the adiabatic curve *DG.* At *G* the high-pressure discharge valves open and the air is discharged into the receiver at the desired gauge-pressure of 100 lb. The shaded portion represents the power saving effected by the inter-cooler.

Fig. 8. ELECTRICALLY-DRIVEN COMPRESSOR

The saving due to the reduction in temperature between stages is not the only advantage of stage compression. The maximum temperature in each cylinder is reduced to a point where the heat can be more thoroughly drawn off by the water-jackets surrounding the cylinder walls; also, the lower temperature in the cylinder is an insurance of good lubrication of piston and valves.

Fig. 9. STEAM-DRIVEN COMPRESSOR

As already indicated, the theoretical function of the inter-cooler in stage compression is to reduce the temperature of the air after it leaves the low-pressure cylinder to the same point at which it was first taken into that cylinder, before it enters the next stage cylinder. Under practical working conditions, however, it will be found that the majority of coolers fail to accomplish this result, and a reduction to within 5 to 10° of the original temperature is considered a good accomplishment.

The inter-cooler consists of a shell containing a nest of tubes arranged in a series of groups through which water flows successively, entering the bottom row and finding an outlet through the top row. Surrounding the water-tubes is a series of baffle-plates, which direct the flow of the air so as to split it up into thin films and ensure intimate contact with the cold water-tube surfaces. By reducing the spacing of these baffles as the high-pressure cylinder is approached, the most efficient velocity of air in transit is attained. When the air comes in contact with the cold-tube surfaces, condensation of the moisture occurs, and it drips and flows down into the bottom of the shell. In order to drain this condensed water the inter-cooler is usually placed at an incline, so that the water will flow into the pocket surrounding the water separator where a drain-cock is provided for the occasional removal of the water. Temperature changes in the inter-cooler cause the tubes to expand and contract, and in order to provide for this it is customary for the best of tubes to be fixed at one end only, while the other end, including the water-box, is left free to move with the tube-plate.

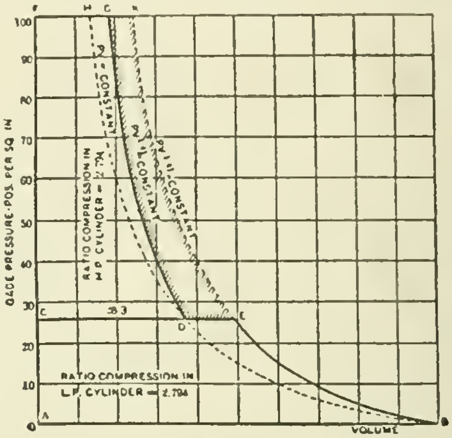

Fig. 10. COMBINED DIAGRAM

As for any other piece of machinery, the load-factor of an air-compressor is the average amount of work actually done, divided by the maximum capacity for work. The result represents the commercial efficiency of the machine, or in other words, the overall cost of production.

It is usual to install an air-compressor to take care of the maximum demand and depend upon some automatic means of regulation or unloading to vary the output of the machine to fluctuating needs. This varies the horse-power input with the load, and effects a saving in cost of operation. It is further usual where the load will vary materially, especially in electrically-driven plants of large capacity, to put in a number of small units and vary the number operating, keeping them at full load to comply with changes of load, to assist in maintaining the highest overall economy. In such cases, regulation depends upon automatic starting and stopping.

The reduction in horse-power input with power-driven air-compressors controlled by some form of part unloading device is not in direct ratio to the reduction in output. For instance, in Fig. 11 is shown a series of cards taken from 28 to 17½ by 21-in. electrically-driven two-stage air-compressor, operating at 185 r.p.m., and equipped with a four-step clearance regulator. It will be noted that at three-quarter load capacity, the horsepower input is 77.5%; at half-load, 55%; at quarter-load, 30%; and at no load 3.6%. The difference is accounted for by the fact that the mechanical efficiency drops off rapidly with a decrease in load; for example, in this particular case at full load the efficiency is 94%; three-quarter load, 92%; half-load, 87.5%; and at quarter-load, 80%.

I. H. P. 15 0% Capacity 3.6% Power

FIG. 11

Air-compressor control-devices are usually set by the manufacturer to meet the conditions imposed by the particular installation, and as the design of these devices varies with the different manufacturers, instructions of only a general nature can be given here. If the device fails to function properly, it is probably due to an obstruction in the way of dirt or other foreign substance, and not to a need for readjustment. It should be thoroughly cleaned and care taken in re-assembling to adhere to the adjustment existing prior to the overhaul.

THE BRADEN MILL in Chile last year produced 192,274 tons of concentrate carrying 21.20% copper, 21.94% insoluble, and 16.10% water as moisture. Seven Marcy mills were added, making sixteen. Thirty Hardinge mills were fitted with new drives and 150-hp. motors. Eight gear-driven M. S. machines of 20 cells each replaced similar belt-driven units.

Costs at the Bunker Hill & Sullivan

During 1918 the mines of this company in Idaho produced 389,027 tons of lead-silver ore. A comparison of mining and milling costs is as under:

	Per ton			Per ton	
Department	1918	1917	Department	1918	1917
Stoping	$1.878	$1.682	Screening	$0.018	$0.011

5% silver discount			93,973
Total smelting cost			$2,144,407
Total cost			$3,584,185

Selling-Value

Production	Quantity	Average price, cents	Amount
Lead, pounds	67,125,717	7.3754	$4,951,847
Silver, ounces	1,191,907	95.8490	1,112,138
Total value			$6,094,285
Less cost			3,584,185
Profit			$2,510,100
Add refund from U. S. government—price concession adjustment			930
			$2,511,030
Kellogg cost per pound, lead, cents			2.14
Smelting cost per pound, lead, cents			3.20
Total cost per pound, lead, cents			5.34

THE DEEPEST SHAFT at Kalgoorlie, Western Australia, is at the Ivanhoe mine, which is bottomed at 3620 ft. Reserves are 1,000,209 tons of $8.16 ore.

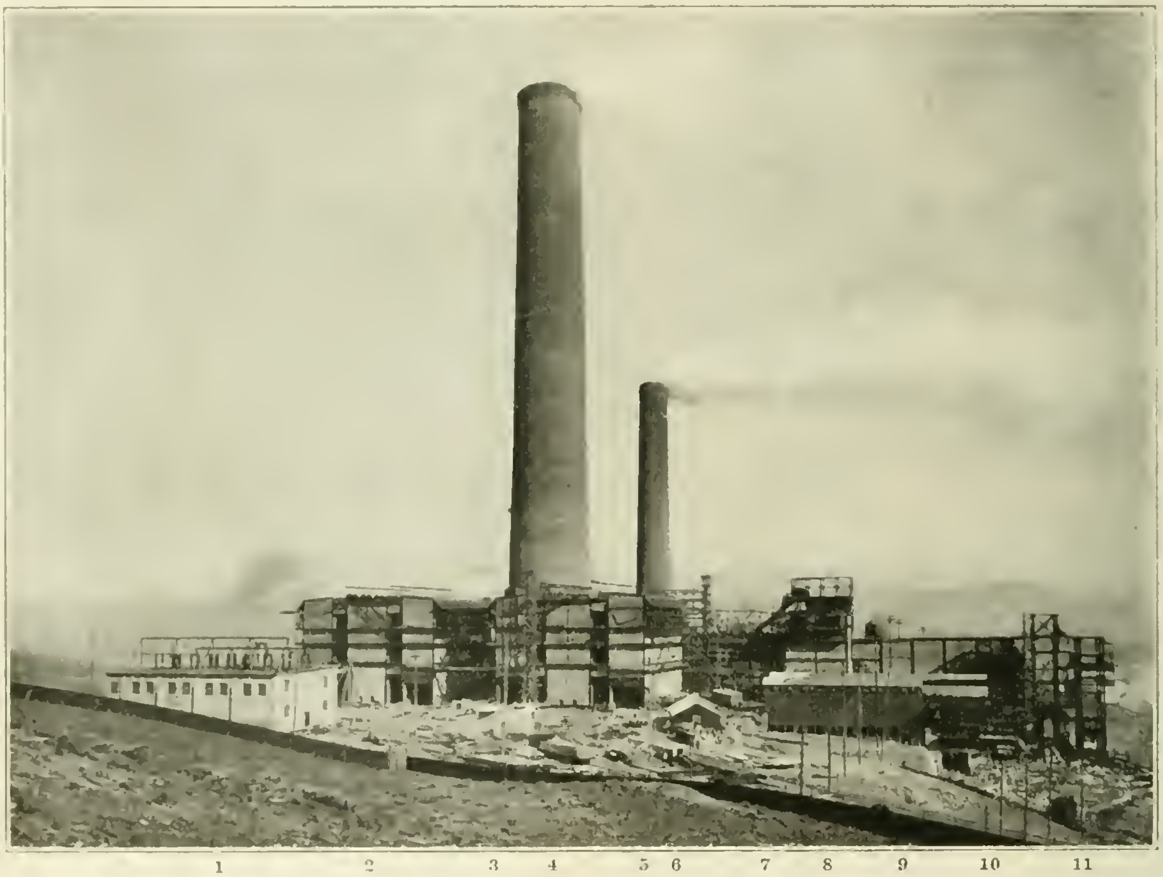
Fire-Prevention in the Butte & Superior

In the annual report of the general manager, J. L. Bruce, the following appears relative to protection against fire in the mine:

Considerable improvements were made during 1918 in methods of supporting and protecting shaft-openings, shaft-stations, skip-pockets, permanent haulage-ways, and other underground openings. Part of these openings have been supported and protected by reinforced concrete; part by a light coating of sand-cement concrete placed directly on the rock or upon reinforcement of wire-netting attached to the timbers; and part by heavy 12 by 12-in. timbers placed face to face to form practically an air-tight timber lining, the latter in many cases being coated by gunnite cement for the purpose of giving additional fire protection and excluding the air. Each of these methods has been demonstrated to be very effective if suitably adapted to the conditions. Underground fire-protection has been greatly improved by the installation of sprinkling rings at intervals in the shafts, and by elimination of inter-communicating openings to other properties. One hundred and ten substantial fire-doors have been completed throughout the mine, and twenty more are under construction. Ten dead-end safety-stations, each isolated from the other mine-workings by fire-doors, have been constructed and equipped with connecting compressed air and water lines to supply air and water in case of emergency. Skip-pockets were completed on the 1600, 1700, 1800, and 1900-ft. levels; the latter, on account of exceptionally bad ground, being built of reinforced concrete in place of the 12 by 12-in. timber-bricking used in the other pockets.

The Anaconda Smoke-Stack

On May 5 smoke was turned into the new smoke-stack at the Anaconda Reduction Works. The top of this chimney is 585 ft.* above the ground, making it the tallest in the world. The vertical flue measures 555 ft. by 60 ft. diameter at the top, and stands on a concrete base 30 ft. high. The accompanying photograph is the first to be made showing smoke issuing from the stack, and was taken 24 hours after the smoke was turned in. The old chimney is still working, as only a portion of the smoke can pass to the new stack pending the completion of the Cottrell installation. At the time the photograph was taken, there were no Cottrell treaters at work, but current has since been turned on at the bank of treaters to the left of the chimney.



1—Cottrell power house
2—10 treaters
3—Cottrell plant
4—New chimney, 585 feet
5—10 treaters
6—Old chimney, 300 feet
7—Flue
8—Cold treater for arsenic
9—Reverberatory for smelting Cottrell dust
10—Flue
11—Hot treater for dust

THE NEW ANACONDA SMOKE-STACK, 585 FT. HIGH

---

*The 'M. & S. P.' of June 29, 1918, gives the height of this chimney as 525 ft. above the foundation. This original dimension was subsequently increased by 30 ft., making the chimney proper 555 ft. and its total height 585 feet.

REVIEW OF MINING

KIRKLAND LAKE, ONTARIO

GOVERNMENT AID TO MINING.—KIRKLAND LAKE MINES.

The Minister of Mines for Ontario, the Hon. G. H. Ferguson, during a trip to the mining districts last week, announced that the Government would undertake several public works in aid of the industry, as follows:

The ore-sampling plant of Campbell & Deyell at Cobalt, the owners of which announced their intention of discontinuing business, has been taken over, and its operation will be continued under the supervision of A. A. Cole, mining engineer for the Temiskaming & Northern Ontario Railway. This will be a great convenience to mining men and prospectors, who would have been seriously embarrassed by the closing of the plant.

In accordance with the wishes of the Kirkland Lake mining companies, who have expressed their preference for a good motor-road rather than a railroad, the Government has finally decided to build a tarvia macadam road from Swastika to the Lake, a distance of 7 miles, at a cost of $10,000 or $12,000 per mile. Another tarvia macadam road will be constructed from Elk Lake to Gowganda, estimated to cost $250,000.

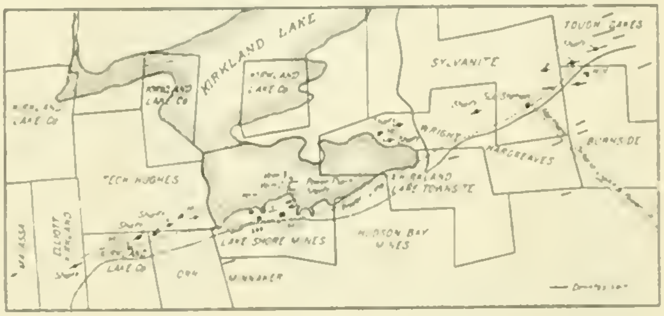
The Government will also contribute a sum not over $30,000 for the construction of a first-class motor-road from the town of Timmins to South Porcupine, thence to the Dome mines, provided that the township of Tisdale contributes an equal amount toward the cost of the road, estimated at $60,000. A steel bridge will be built across the Matagami river.

The Toronto Standard Stock and Mining Exchange has put in force one of the safeguards included in the blue-sky law, which failed to secure adoption during the last session of the Legislature. In order to prevent the marketing of worthless or doubtful shares, it has adopted a rule that before a company can be listed, the promoters must agree that at least 50% of the money realized by sales will be used for development work.

Kirkland Lake.—Reports of two companies operating here have been issued for the past year:

The Beaver Consolidated Mines of Cobalt controls the Kirkland Lake Gold Mining Co., which owns 362 acres at Kirkland Lake. Development so far (5210 ft. to a depth of 700 ft.) has been confined to a vein that has been traced on the surface a distance of 1400 ft. Seven levels have been opened by No. 2 shaft, and the main shaft is to be sunk to connect with it at 600 and 700 ft. depth. About 8000 tons of ore has been raised to the surface for milling. The 150-ton plant consists of a crusher, 500-ton bin, Buchanan jaw-crusher, magnetic pulley, trommel, Tellsmith crusher for trommel oversize, ore-bin, 8 ft. Hardinge ball-mill, Dorr classifier, tube-mill, and 15 solution tanks, pumps, presses, etc., for the counter-current decantation cyanide process. For the mine there are 4 and 10-drill Sullivan steam-driven compressors, a 12-drill electric-driven compressor, double-drum electric hoist, shop, bunk-houses, and all necessary buildings.

At the Lake Shore Mines at Kirkland Lake, R. C. Coffey is mine manager. During the year ended November 30, 1918, receipts were $374,074, of which $144,978 was net profit, after allowing $90,000 for exhaustion. Current assets were $186,996, and liabilities $84,842. Payment of dividends and subscription to the Canadian Victory Loan totaled $150,000. No. 1 dividend, on August 20, and No. 2, on December 10, 1918, absorbed $100,000. A total of 2961 ft. of development was done on No. 1 and 2 veins; of the driving, 80% was in ore of milling grade. No. 1 vein was further opened on the 100, 200, 300, and 400-ft. levels, and No. 2 at 200 and 400 ft. The ore-lenses persist in size and value at the lowest level. The new mill commenced work in March 1918, and treated 11,948 tons of $24.76 ore. The operating cost of $158,176 is equal to $10.58 per ton. During April 1919, $14,782 was extracted from 1800 tons of ore. An assay-office, refinery, bunk-house, ice-house, bungalows, cottages, and other necessary buildings have been erected.



MAP OF THE KIRKLAND LAKE GOLD PROPERTIES

The Tough-Oakes company during April did 1016 ft. of exploration. Seven machines and 98 men were employed. A new vein of $20 gold ore was found. The mill is not in operation yet. The net working capital is now about $150,000. H. H. Johnston is in charge.

The Teck Hughes in April treated 2602 tons of $10.46 ore. D. L. Forbes is manager.

The Ontario-Kirkland has cut its vein at 300-ft. depth, there being 5 ft. of good ore with some visible gold.

HOUGHTON, MICHIGAN

LABOR AND ORE PRODUCTION.

The exodus of men from the Copper Country continues, 275 receiving settlements during the past week. Forty were laid off at Allouez, 50 at Osceola, and more at Centennial. Isle Royale continues to decrease its men, and ore shipments are only 60,000 tons per month. Ore from the Superior goes to the Tamarack mill. Centennial plans an extensive scheme of development, with further curtailment in copper output. Calumet & Hecla is erecting machinery for the additional flotation plant at the mills. Dismantling of No. 2 shaft rock-house is still under way. Pillars have been taken out to No. 7 level. There is plenty of rich ore above, but it cannot be moved as valuable surface plant is situated above. Hecla No. 12 shaft is now used exclusively for timber and supplies. It will be four months before the miners hole through for the lateral to permit transfer of Hecla ore to the Red Jacket shaft. No. 3 Tamarack shaft, now part of C. & H., is working but one shift.

During April the mines of the 'Copper Country' produced the following ore and metal:

Mine	Tons	Copper content., lb. per ton	Output, lb.
Ahmeek	64,790	...	1,490,311
Allouez	20,000	17.7	355,480
Baltic	22,000	34.0	748,000
Calumet & Hecla	218,082	20.0	4,361,645
Centennial	7,020	16.0	114,652
Champion	38,000	36.0	1,394,000
Franklin	25,135	10.0	251,350
Isle Royale	58,400	17.0	993,073
La Salle	850	20.0	17,000
Mass Consolidated	10,000	20.0	200,000
Michigan	5,240	30.0	157,000
Mohawk	49,000	24.0	1,176,000
Osceola	68,960	13.9	950,579
Quincy	100,000	17.0	1,700,000
Superior	3,700	20.0	74,000
Trimountain	15,000	26.0	390,000
White Pine	11,600	17.0	197,373
Wolverine	22,800	21 6	493,860

The White Pine mine, in Ontonagon county, a subsidiary of Calumet & Hecla, has suspended operations, not through any physical condition, but because the company had run out of cash. No. 2 shaft is down 1600 ft., of which 581 ft. is vertical, 392 ft. curved, and the remainder 45° underlay. All underground openings are generally better than before.

COBALT, ONTARIO

LABOR AND DEVELOPMENTS.

The number of men employed in the mines is considerably smaller than a year ago. The reason is that the standard of efficiency is much higher, and only competent workers are retained. This step was rendered necessary owing to the great increase in operating costs last year. This is being gradually reduced by higher labor efficiency and some decline in the price of supplies.

The recently installed electric-haulage system at the Crown Reserve is working satisfactorily. It is the first to be used at Cobalt, though the system has been adopted successfully by the Hollinger and McIntyre mines at Porcupine.

At the Adanac, high-grade ore is being taken from three veins. A vein 6 to 10 in. wide, with high-grade spots, is being opened in a winze below the 310-ft. level. A 2-in. high-grade vein has been cut on the Ophir at a depth of 600 feet.

An important strike has been made on the 600-ft. level of the Beaver, consisting of a 4-in. vein, said to carry between 2000 and 3000 oz. per ton.

GOLDFIELD, NEVADA

REVIVING THE CACTUS SILVER DISTRICT, ALSO THE TULE CANYON GOLD DISTRICT.

Joseph F. Nenzel of Rochester and associates have purchased seven claims in the Cactus district, owned by M. E. Bailey of Goldfield. Cactus is 24 miles east of Goldfield and, aside from work done by Bailey, there has been little development there for many years. Bailey sank two 100-ft. shafts and one 150-ft. shaft in a vein 2000 ft. long and from 2½ to 6 ft. wide, the average width being 4½ ft. John R. Magill, superintendent for a company organized to develop the claims, the Cactus Nevada Silver Mines Co., says that assays obtained on the surface show the entire outcrop to be good-grade milling ore. The average assay return is said by men interested in buying the claims to have been $25 per ton. From 90 to 95% of the value of the ore is in silver, the remainder in gold. The vein is in a contact of rhyolite and andesite, and the silver is in sulphide form. A fractured zone two miles long extends through the district, with a series of parallel veins, three of which strike almost due north through the group bought by Nenzel. All work done by Bailey is on one vein. Good assays have been obtained from another vein 600 ft. to the west, which is from 6 to 8 ft. wide. The new company has $30,000, and proposes to sink the 150-ft. shaft an additional 350 ft., and do 3000 ft. of lateral work at this depth. Since Nenzel entered the district a number of others have become interested in claims, and groups adjoining the Cactus Nevada will be opened. Buildings, machinery, and supplies are being hauled from Goldfield. The road from here to Cactus is in excellent condition, and Nye county is repairing the road from Tonopah, which is 29 miles north-west of Cactus.

The Ingalls mine in Tule canyon has been sold for $100,000 to Patsy Clark, a mining man of Seattle and Butte. The Borcherding-McDermitt-Hill lease on the entire mine and the 15-ton mill owned by the lessees have been sold to Clark for $75,000. The first payment of $25,000 has been made; the second installment is due in 60 days. According to Borcherding, who, with John Creighton of Elko county, negotiated the sale, there is 100,000 tons of $40 ore exposed in the mine, which, during the 30 years it was owned by Sheriff Ingalls of Esmeralda county, is said to have produced $200,000. The vein has been opened for a distance of 3000 ft. and to a depth of 100 ft. The average width is 6 feet.

The Goldfield-Tule Canyon Placer Mining Co. has started drift mining. This company owns 1½ miles of placer ground in the canyon, adjoining on the north the 6 miles of claims owned by a company of Goldfield men, in which A. I. D'Arcy is heavily interested.

SAN FRANCISCO, CALIFORNIA

STATISTICS OF OIL AND NATURAL GAS IN CALIFORNIA.

Compilation of the quantities of oil and gas produced throughout the State during 1918 has just been completed by the State Mining Bureau. The amounts are based on sworn statements from all producers. The total petroleum production is 99,459,177 bbl. This is an increase of 5,025,630 bbl. over 1917, and 12,395,982 bbl. more than the production of 1916. The yield for 1918 is second only to that of the year 1914, and demonstrates that the contention that regulation hinders development has no basis in fact.

The official totals are less than those published by private concerns such as the Independent Oil Producers' Agency and the Standard Oil Co. The latter, however, makes no allowance for water and other impurities in the oil when first produced and gauged. Aside from these differences, it should be noted that these private concerns have regularly supplied the public with accurate information.

There were no additions of importance, during 1918, to the proved oil-lands determined by the State Mining Bureau for the assessment of 1917. The total proved acreage is 89,212, showing an increase of 1852 acres over the year 1918. The rate of assessment, levied to support the work of supervision of drilling operations so as to prevent the fields from damage by water and other causes, is based upon the quantities of oil and gas produced and the proved oil-land. The rate for the coming year amounts to $0.001076 per barrel of oil or 10,000 cu. ft. of gas produced, and $0.137 per acre of proved oil-land. The amount to be collected is $123,000, and is $6000 less than the total assessment for last year.

The figures in detail, showing comparative productions of oil and gas for 1917, are as follows:

	Oil, bbl		Gas, 10-M cu ft		Land	Wells
Counties	1918	1917	1918	1917	acres	No
Fresno	16,068,919	16,146,797	80,300	59,189	13,319	1108
Kern	49,049,917	52,688,711	1,987,821	1,927,506	57,499	4926
Los Angeles	9,853,190	4,357,162	162,692	24,175	2,873	783
Orange	15,730,462	14,568,930	903,530	655,027	3,530	504
Ventura	1,339,342	989,726	10,481	......	1,776	374
Santa Barbara...	7,334,104	5,589,223	71,313	60,157	9,363	412
San Luis Obispo.	62,744	74,143	......	......	772	13
Santa Clara	20,499	18,855	......	......	80	8
Total	99,459,177	94,433,547	3,216,119	2,726,051	89,212	8188

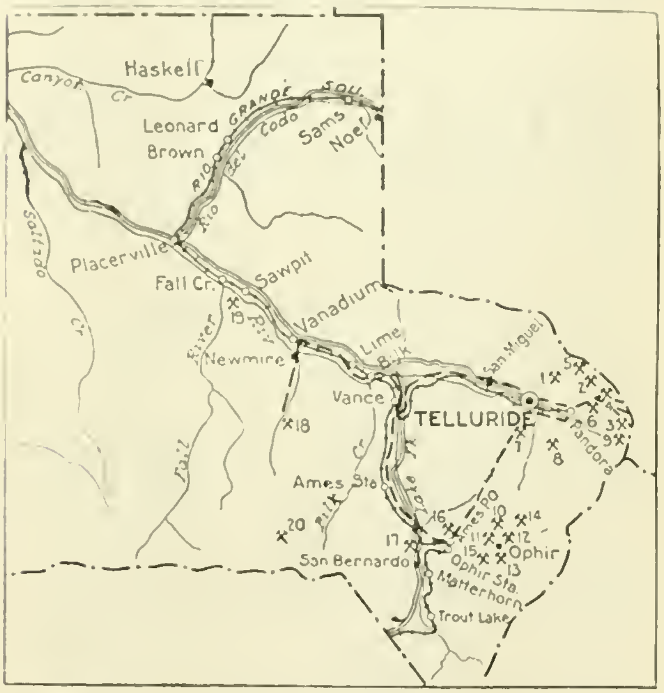
Oil-field operations reported to the Bureau for the week ending May 10, show 17 wells ready to drill, making a total of 218 wells since the first of the year. Seven of the wells reported are to be drilled in the new Richfield field in Orange county.

TELLURIDE, COLORADO

POWER IN PLENTY AGAIN.—SNOWSLIDES A NUISANCE.—WORK RESUMED AT SEVERAL MINES.

The district is very active. The power supply is now abundant, permitting the Liberty Bell to resume operations, while the Belmont Wagner will start its mill earlier than expected. A shortage of labor still prevails, notwithstanding the high wages and the large number of miners released from the Sunnyside mines.

Snowslides were running again during the latter part of April and early in May, the result of warm weather. Such slides are known as 'wet slides', and are generally of mixed snow and mud. Such slides occurred at Ames, on the Rio Grande Southern railroad during the latter part of April, blocking all traffic for a few days. The great trouble and interference with traffic occasioned by the slides during the past winter has led to an investigation into some method of overcoming them, and through co-operation of railroad officials and mining companies of Telluride a plan is under consideration to drain the low marshy plateaus that lie at the head of the cuts, particularly at Ames, thus causing a drying out of the land. The general opinion is that were such places drained there would be no accumulation of water during the melting season, which is the principal factor in causing the mud-slides. A large wet slide occurred at Pandora Park on April 18, damaging pipe-lines leading to the Pandora mill and stopping operations for a few days. On April 20 a slide ran from the Ophir tunnel of the Tomboy, carrying out 50 ft. of tram and smashing in the terminal building, but fortunately not damaging the machinery.



NUMBERS ON MAP REFER TO THE FOLLOWING MINES:

(1) Liberty Bell; (2) Smuggler Union; (3) Tomboy; (4) Japan; (5) Sheridan; (6) Bob Tail; (7) Contention; (8) Ballard; (9) Colorado Superior; (10) Alta; (11) Suffolk; (12) Highland Mary; (13) Favorite; (14) Carbonero; (15) Caribeau; (16) Silver Bell; (17) Butterfly; (18) Primos; (19) Primos; (20) Silver Pick.

THERE ARE 8 AERIAL TRAMS IN THE DISTRICT, WITH A TOTAL LENGTH OF 11 MILES.

The higher price of silver has resulted in re-opening of the Humboldt workings by the Smuggler Union company. The men employed at the Black Bear will be diverted to the Humboldt. The cross-cut to the Bullion tunnel is now finished after 2 years' driving. Black Bear operations will be curtailed until the mill is enlarged, which has only sufficient capacity to treat the ore from the main Smuggler properties.

PLATTEVILLE, WISCONSIN

CONDITIONS IN THE ZINC FIELDS DURING APRIL.

The general status of zinc mining, heavy rains, interruption of power service, and a hesitancy to reduce wages, all tended to make April a poor month in the Wisconsin fields. A heavy reserve of zinc concentrate, carried over from the beginning of the month, was kept down by great effort and through important shut-downs. It now totals 10,000 tons. The Kennedy mine, at Hazel Green, owned and operated by the New Jersey Zinc Co., suspended operations after 30 years of consistent production. The Block-House mine at Platteville, for several years very profitable, suspended operations. Unsold zinc oxide, manufactured from raw carbonate ore, contributed further to a discouraging position. Of four blocks of furnaces usually operating at the works of the Mineral Point Zinc Co., only two blocks were kept hot during April, and every available space contained unsold oxide officially reported to your correspondent as amounting to nearly 10,000,000 lb. Acid plants were running at about half of normal capacity, three cars of commercial sulphuric going out weekly, whereas under better conditions shipments are from six to ten cars. Local electro-static zinc-ore separating-plants did their level best to make profits.

VICTORIA, BRITISH COLUMBIA

MINERAL AREAS OF ALBERNI CANAL.—COPPER AND BLACK SANDS.

Victor Dolmage, of the Canadian Geological Survey, to whom was assigned the work of a reconnaissance survey of the mineral areas of the northern portion of Vancouver Island during the season of 1918, after having gone over the district contiguous to Quatsino sound, cruised down the west coast of the Island and for three weeks examined as many mineral districts as possible. Owing to the lateness of the season and to the fact that local guides were not always available, many of the deposits, and in some cases the best, were not examined. Some prospecting was done during the trip, and such observations on the geology of the region made as would suffice to outline plans for future work.

One of the properties visited by Mr. Dolmage was the Indian Chief, situated on Sidney inlet. This is one of the only two claims in this portion that has reached the shipping stage—the other shipper being the Monitor, near the entrance to Alberni canal. The Indian Chief claims, now owned and operated by the Tidewater Copper Co., have been worked at many times and by many different companies since 1897, and have produced a lot of high-grade ore. At present it is equipped with a small oil-flotation concentrating-mill, which is on the beach, connected with the mine by aerial tram. The ore, consisting of bornite with small quantities of chalcopyrite and chalcocite, occurs in a garnetized limestone, capping a hill composed of grano-diorite. The limestone, except at the top of the mountain, is metamorphosed, and signs of mineralization are plentiful. Some rich lenses of bornite have been extracted from both the north and south sides of the hill, and some smaller ore-shoots have been discovered in the main tunnel on the south side. The mill, which was completed only a little over a year ago, was operated for a few months only and at a considerable loss. This was partly due to unsatisfactory machinery, and partly to an irregular supply of ore, often too low-grade. The mill was shut-down and a shipment of picked ore was made direct to smelter. At the time of the examination, a small force of miners was carrying on development work in the main tunnel.

The Monitor group of claims is on the north shore of Alberni canal, just at its entrance. The mineralized zone extends back from the shore several thousand feet. The property was discovered in 1898, and during 1900 and 1901 steadily produced ore, which was shipped to the Tacoma smelter. From 1902 it remained virtually idle until 1916. The present owner, Leonard Frank of Alberni, bought the property some years ago at a tax sale. Since 1916 it has been leased to James Skeen of Seattle, who has done considerable work on the various exposures that have been discovered since his taking charge, and has erected a good deal of expensive equipment. The ore consists of pyrrhotite and chalcopyrite, with small quantities of magnetite and pyrite. It occurs chiefly in the altered limestone, which consists of calcite, quartz, garnet, epidote, and actinolite. Some of the ore is found in the metamorphosed volcanic rocks, which are altered to epidote, chlorite, and hematite. Like all the deposits of this type found on the west coast of Vancouver Island, the ore is very irregular and the value of the mine, therefore, difficult to estimate. A considerable tonnage of ore averaging 8% copper has been blocked out, and in the new workings there are large lenses of concentrating ore of medium grade; but it is doubtful whether sufficient ore has been exposed to warrant the installation of a concentrating plant. At the time of the examination the mine was closed on account of financial difficulties. A visit was also paid to the Wreck Bay beach placers, lying between Kennedy lake and the West Coast of the Island, and extending from Ucluelet to Tofino inlet in a flat coastal plain composed of unconsolidated sands, fine gravels, and thin beds of blue clay. The plain is 60 ft. above sea-level, and is bounded along the coast by a perpendicular wave-cut cliff at the foot of which is a beautiful beach sloping gradually out to sea. These sediments contain a small quantity of black sand and fine gold which is being continually concentrated at the base of the cliff by the action of the waves. Prospectors and campers came periodically and cleaned-up the gold by panning the black sand found at the foot of the cliff. Several attempts have been made recently to use small concentrating machines operated by hand or by gasoline engines, but the amount of sand is too small for continuous operations and is soon worked out. A number of years ago some of the local settlers organized a company and built a flume and sluice-boxes, from which were obtained several thousand dollars worth of gold, this being the first time these wave-washed concentrators had been worked.

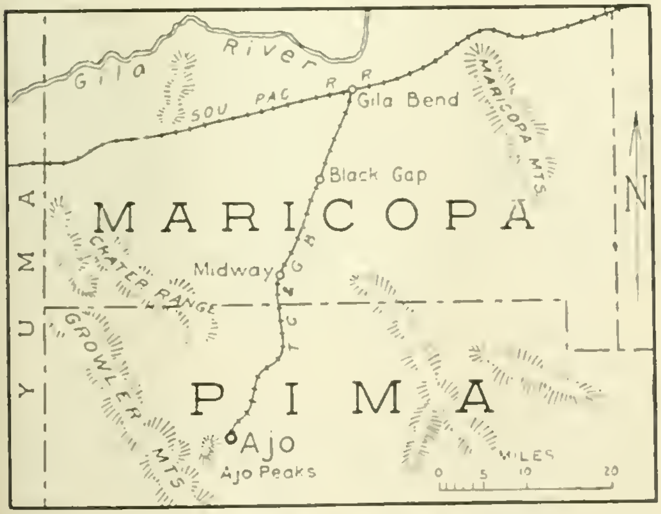
THE MINING SUMMARY

Gold producers in the United States should procure a copy of Bulletin 144 of the U. S. Bureau of Mines, which has just been issued, and is entitled 'Report of a Joint Committee Appointed from the Bureau of Mines and the U. S. Geological Survey by the Secretary of the Interior to Study the Gold Situation'. The committee consisted of Hennen Jennings, Charles Janin, J. H. Mackenzie, F. L. Ransome, and H. D. McCaskey. Their findings have been given in the 'Press', but this 76-page report is valuable in that it is replete with graphs and tables of production, costs, and wages.

ARIZONA

Ajo.—New Cornelia produced 2,674,000 lb. of copper during April, compared with 4,318,000 lb. in January.

The Ajo-Cornelia Copper Co. has been reorganized by Ajo business-men, who are now in control of the company. The offices are to be moved from Miami. This company owns 14 claims adjoining the New Cornelia on the east. There has been some shallow development work done and a diamond-drill hole put down 800 feet.



PART OF ARIZONA, SHOWING POSITION OF AJO

Chloride.—The Hackberry Consolidated Mines Co. is to increase its capital from 1,000,000 shares, $1 par, to double that amount. The money will be for further development and to bring the mill to the rated capacity of 250 tons daily. The plant is at present treating 80 tons in 10 hours, but another shift is to be put on shortly. The flotation plant is making a high recovery in charge of T. D. Walsh. William Neagle is general superintendent of this silver property.

The Rural and Buckeye gold-silver mines in the Mineral Park district have been taken over by M. B. Dudley and New York people. These mines yielded rich silver ore years ago. They were recently examined by W. W. Widdowson and G. W. Schilling. It is estimated that 22,000 tons of high-grade milling ore is available, plus 8000 tons of milling ore on the dump. The Rural shaft is 200 ft. deep, and from samples taken at the bottom there were high assays returned. The Buckeye has a 700-ft. tunnel, following the vein most of this distance, at least 500 ft. A large tonnage from this has been sent to smelters, and above this level is the milling ore. Tests are to be made on the ore, and a 100-ton mill is contemplated. The properties are favorably situated for power, roads, and rail, the last being only 5 miles away.

Jerome.—The United Verde and Extension Companies are to resume mining at about half capacity. The former is to raise its No. 6 shaft from 1650 to 430 feet.

CALIFORNIA

Downieville.—According to J. R. Hodges, in charge of the Hidden Nugget gravel claim on Kanaka creek, the company is to let a contract for driving the tunnel 300 feet.

Grass Valley.—The Empire Mines Co. is preparing to erect 20 additional stamps, to be ready early in the fall.

M. J. Brock has transferred all of his mining property within the city to the Grass Valley Boundary Mines Co., including the Oak Tree, New Idea, and Cabin Flat quartz claims, together with the mineral rights under several lots on Pleasant street. A complaint over mining ground that promises considerable interest and to be long drawn out, was filed in the Superior Court of Nevada county on May 21. The newly organized Grass Valley Boundary Mines Co. commenced an action against the Center of Grass Valley and the Golden Center of Grass Valley mining companies to quiet title to mineral rights to certain lots in the heart of Grass Valley, and claimed by defendants.

Sheridan—The Rock Creek mine in Placer county is under option to W. B. Swears of San Francisco. The controlling interest was recently taken over by Buckeley Wells and associates. H. H. Ray is in charge of the mine, and has 15 men working.

COLORADO

Boulder.—The Colorado Pitchblende Co., according to the 'Salt Lake Tribune' of Utah, has opened an office in Salt Lake City, in charge of J. F. Brim. It is said that Utah capital is largely interested in this much-advertised company, and that the 100-ton mill will be increased to 500 tons capacity by adding a few tables.

The Colorado Pitchblende Co. has acquired a power-plant and water-rights in South St. Vrain canyon, including 160 acres of timber land.

The fiftieth anniversary of the discovery of the Caribou silver lode is to be celebrated here, and the Boulder County chapter of the Colorado Metal Mining Association has the matter in hand.

The Golden Cycle Mining & Reduction Co. of Colorado Springs has entered this district by issuing a schedule of freight and treatment rates for gold-bearing ore sent to its works.

Leadville.—The principal silver sections of this district—Iowa Gulch, St. Kevin, and Sugar Loaf—are to be exploited to a much greater degree than formerly, new work being in progress.

IDAHO

Kellogg.—The town has received $2806 from the Mine Owners' Association, being a reimbursement for money expended by the town during the floods of May 1917 and of

January 1918 in protecting property. A tailing dam of the Association at Osborne broke from the high waters of these floods and caused the river-bed to become filled with tailing and the river to spread out over its confines.

Talache.—The Armstead company on Pend Oreille lake in Bonner county has finished the 3-compartment raise from No. 3 to No. 2 tunnel, a height of 600 ft. The connection was perfect, as surveyed by Carl Wilson of Sandpoint. The raise is inclined. No injuries were reported during the work done in charge of W. A. Hackett. A mill is being designed by O. B. Hofstrand of Salt Lake City. There are 40 men employed in charge of D. G. McLachlan.

Wallace.—Wages in the Coeur d'Alene region were raised from $4.25 to $4.75 per day on May 20. During March there was a cut of $1.

Federal Mining & Smelting pays a dividend of 1%, $1 per share or $120,000, on June 14. This makes $14,884,350 to date.

The net profits of mining companies operating in the Coeur d'Alene region in 1918 was $7,272,475, according to reports filed with the auditor of Shoshone county. First place is occupied by the Hecla with $1,984,920, second by the Hercules with $1,915,766, and third by the Bunker Hill & Sullivan with $1,379,318. The total value of the production by 14 companies was $24,093,203 and the total extraction by 13 companies was 4,447,120 tons. The only deficit is shown in the report of the Mace mine of the Federal company, which lost $5587. Several reports remain unfiled.

The Big Creek Mining Co., operating in the Evolution district, is to erect a 60-ton mill for its lead-silver ore. The property was recently examined by F. J. Davey of Wallace. G. S. Anderson is president.

MICHIGAN

Houghton.—The Franklin Mining Co. has levied an assessment of $1 per share, due on June 3. This will yield $166,000.

MISSOURI

Jefferson City.—A bill to impose a tax of 2% on the gross receipts of all zinc, lead, barite, and other mineral mines of the State failed to pass the Missouri Legislature.

MONTANA

Butte.—Davis-Daly has connected the 2500-ft. level of its Colorado mine with that of the Anaconda company's Belmont mine, resulting in proper ventilation of the lower levels of the former. Davis-Daly will soon be able to produce over 400 tons of copper ore daily. The Hibernia mine contains zinc ore high in silver, but on account of apex troubles no mining is being done there.

Butte & Superior is reported to have cut 8 ft. of rich zinc-silver ore on its 1900-ft. level.

Neihart.—The Cascade M. & M. Co. has cleared out the old Broadwater mine tunnel for 2000 ft., and exploration is under way. The old ore-shoot that yielded over 6,000,000 oz. of silver years ago is exposed for 1000 ft. in the lower tunnel-level, and it is estimated that there is 150,000 tons of 20-oz. ore above that point.

At the Moulton a winze is down to a depth of 585 ft. in the orebody. The mill is treating 135 tons daily, but additions will soon bring its capacity to 225 tons.

Philipsburg.—Lessees at the Scratch Awl property have opened a considerable quantity of rich silver ore. One carload carried nearly 300 oz. per ton. George Nevling is largely interested.

Troy.—The Snowstorm Mines company is in need of 50 miners. A 150-men capacity dry-house is being erected, and a row of 6 to 8-men bunk-houses. The advance in price of silver has added $3 per ton to the value of the lead concentrate produced.

NEVADA

Divide.—Fifty-four operating companies have organized the Divide Mine Operators Association, with the following officers: A H. D'Arcy, president; J. W. Hutchinson, vice-president; R. J. Davey, secretary and treasurer; E. J. Roberts, J. K. Turner, Allan Rives, L. R. Robins, H. F. Bruce, J. W. Hutchinson, and A. I. D'Arcy, executive committee.

There has been a considerable slump on the price of shares in this district, notably the Tonopah Divide, which fell from $11.50 to $7.60. Others show much lower prices.

The Tonopah Divide has its 1200-cu. ft. compressor in place and air-pipes laid to the working points. The important work in hand is opening the ore-channel on the No. 5 level and advancing the main south-east drift on No. 4. The output of ore last week was 420 tons.

The Gold Zone has finished installing electric motors in the hoist and compressor-house. Sinking to 800 from 500 ft. is to be started, and development of the encouraging exposures at 500 feet.

The south-east part of the Divide district is attracting attention. Here are the Ben Hur, Rosetta, Gold Wedge, Gold Team, Silver Divide, Belmont, and a score of others.

Eureka.—An air-compressor and machine-drills have been installed at the Silver Connor, on the west side of Prospect mountain. Re-timbering of 700 ft. of raises from the Prospect tunnel has been finished.

Goldfield.—Grandma Consolidated has issued a report covering 8 months ended February 28, 1919. Continuous development resulted in 443 ft. of new work. Shaft work cost $47.10 and cross-cuts $21.83 per foot. The shaft is 827 ft. deep. At 775 ft. the shaft entered the main Grandma-Spearhead formation, and continued in it until the shale was reached at 810 ft. Encouraging value was found to this point. A drift south on the 800-ft. level was driven 40 ft. in vein-matter of low value, so the formation was cross-cut, showing it to be 100 ft. wide. A north-westerly drift in the formation was out 155 ft. at the end of February. In the report of J. K. Turner, he considers that results are encouraging. A pump, compressor, motors, and other machinery were put in during the period.

Goodsprings.—The Yellow Pine Mining Co. is to resume work early in June, according to M. P. Kirk, the general manager.

Imlay.—Containing numerous veins assaying high in silver, gold, and lead, the Richland mining district, eight miles from Imlay, has been organized. It lies north of the Humboldt river, on the south slope of the Eugene mountains. Sampling of several claims shows assays ranging from $11 to $43 in gold and silver and 11 to 18% lead. Claims have been acquired by prominent Nevada men, including H. G. Humphreys, George B. Thatcher, and R. M. Preston of Reno, and T. J. D. Salter of Winnemucca. The Richland Mines Co. has been formed to develop several groups. J. R. Tullis of Imlay is president; J. W. Ferguson of Winnemucca is secretary; and C. T. Smith of Imlay is managing director.

Manhattan.—The White Caps company is stoping above No. 4, 5, and 6 levels, and is to sink a winze on the orebody from No. 6. With depth, the ore carries more sulphur, and roasting is now done practically without using any oil; in fact, last week the furnace worked one day without any fuel. The stack has been altered to eliminate fume and give better draft.

Mina.—The Copper Dome property, 25 miles east of Mina, has been taken under option by the Phelps Dodge Corporation, according to Louis Sirac, principal owner. The Copper Dome is three miles east of the Simon silver-lead mine, in the Cedar range, and comprises six claims. Large formations of copper-bearing ore traverse the claims, with the principal vein about 100 ft. wide. Prospecting indicates the copper is replaced at fair depth by silver-lead A thorough test of the property is to be made with diamond-drills

The Simon Silver Lead Mines Co has decided on the erection of a 200-ton flotation plant at the property, 22 miles east of Mina. The orebody has been opened for a length of 300 ft. on the 300-ft. level, with the cross-cut showing the deposit to be 77 ft. wide. Between the 230 and 300-ft. levels there is estimated to be 140,000 tons of sulphide ore. The zinc content decreases with depth. The shaft is 400 ft. deep and water is flowing in at the rate of 20,000 gal. per day The gasoline hoist, compressor, and pumping plant are to be replaced with heavy electrically-driven machinery. P. A. Simon is manager and O. E Schiffner superintendent

Virginia City.—Last week the Con. Virginia produced 322 tons of ore valued at over $8000, and the Ophir 296 tons worth nearly $9000. At 2050 ft. in the former, the ore assayed $46.27 per ton. The 2100 and 2150-ft. levels are also yielding rich ore. The Ophir is working at 1900 and 2000 ft. The Mexican mill treated last week 351 tons of $26.12 ore from the Con. Virginia, and 215 tons of $30.13 ore from the Ophir. Bullion worth $20,000 was sent to the San Francisco Mint.

NEW JERSEY

Franklin.—The New Jersey Zinc Co.'s income during the first quarter of 1919 was $2,855,427, compared with $5,338,796 in 1918. Federal taxes amounted to $570,000. After distributing $1,400,000 in dividends the surplus was $770,427, against $2,203,796 in that period of 1918.

SOUTH DAKOTA

Lead.—The Custer Peak Mining Co.'s new 100-ton dry concentrator at the Jungle mine is in operation. The ore averages 4% copper.

Rapid City.—The 'Pahasapa Quarterly' of the South Dakota School of Mines is a 'good roads number'. The State Legislature at Pierre, during the session ended March 9, 1919, appropriated $6,817,296 for road work. A new highway law was passed also. The Federal government has allotted $4,458,545 for highways. The mining counties of Lawrence, Pennington, and Custer will benefit thereby.

TENNESSEE

Copperhill.—The Tennessee Copper & Chemical Corporation is to raise $4,400,000 by the sale of 400,000 shares of new Tennessee stock to present holders on a share-for-share basis at $12.50 each. This money will be spent in developing a phosphate rock deposit, erecting plant, and making superphosphate, a fertilizer, using the acid made for this purpose.

Ducktown.—The School property here has recently been transferred to the Copper Pyrites Corporation of New York. Shipments of pyrite averaging 40% sulphur will probably begin about the middle of May. There is now available 50,000 tons of pyrite, besides large bodies of low-grade copper-bearing pyrrhotite, which will later be mined and treated by differential flotation for its copper content, according to R. R. Horner of the U. S. Bureau of Mines.

UTAH

The 'blue sky' law for this State went into effect on May 12. Brokers handling treasury or promotion stock after May 13, 1919, will be required by the State Securities Commission to file a bond of $5000 and secure a license from the Commission. Companies whose stock is listed on the Salt Lake Stock and Mining Exchange, and whose directors or agents are disposing of treasury stock through members of the Exchange, or any of whose directors or agents are disposing of promotion stocks through members of the Exchange, are required by the State Securities Commission to take out a license as an investment company.

PERSONAL

Note The Editor invites members of the profession to send particulars of their work and appointments The information is interesting to our readers

John M. Boutwell is at Lima, Peru.

Arthur L. Pearse, of London, is at the Palace hotel.

G. R. Allen left San Francisco for the Orient on the 'Korea' on May 21.

Frank W. Oldfield, manager of the Cinco Minas, Jalisco, Mexico, is in New York.

Frederic R. Weekes has moved his office from 42 Broadway to 233 Broadway, New York.

Tomizo Sasabe, of the Mitsubishi Mining Co., is visiting the gold mines of Grass Valley, California.

George J. Bancroft, of Denver, is opening up the War Eagle copper mine, near Warren, in Idaho county.

Bailey Willis read a paper on the 'Structure of the Coast Ranges' before the Le Conte Club, in San Francisco, on May 23.

J. L. Rosenshine has succeeded **H. A. Barker** as manager for the Sociedad Explotadora de Caylloma Consolidada, at Arequipa, Peru.

Edwin S. Church, of the Wellman-Seaver-Morgan Co., delivered the commencement address to the Colorado School of Mines on May 23.

A. W. Stickney sailed for Siberia on the 'Empress of Russia', which left Vancouver on May 29. His address is care British Trade Commissioner at Vladivostok.

J. J. Shaw, for the past three years manager for the syndicate Mining Co. at Aroroy, has returned from the Philippine Islands and is registered at the Stewart hotel.

H. Foster Bain, who has been serving as Assistant Director of the U. S. Bureau of Mines, has resigned to resume exploration in the Far East. He sails for China from Seattle on June 12.

Thomas S. Chalmers, Major in the U. S. Engineers, has returned from France after being 21 months in the Army. He has returned to business as president of Chalmers & Williams, at Chicago.

William Neill, manager for the Cassel Cyanide Co., of Glasgow, Scotland, is touring North American mining districts. He was recently at Cobalt, Ontario. He has visited several Mexican mining districts.

William Frazier, superintendent for the Davis-Daly Copper Co. since 1907, and much respected at Butte, Montana, died on May 17, aged 44. He went to Butte in 1893, being connected with the late F. A. Heinze.

T. M. Owen, mill-superintendent for the Federal Mining & Smelting Co. at Wallace, Idaho, has gone to Australia to investigate the status of flotation in that country. He came from Broken Hill to the United States six years ago.

James Johnston, for many years mill-manager for the Nipissing Mining Co. at Cobalt, has resigned, and is on his way to England, where he will engage in consulting work with **Charles Butters**, with offices at 120 Bishopgate, London.

Victor C. Alderson, president of the State School of Mines at Golden, Colorado, with **Harry J. Wolf**, **I. A. Palmer**, **F. M. Van Tuyl**, and **Samuel Z. Krumm**, professor in that institution, are making an examination of the Cripple Creek district, including mining, metallurgical, and economic problems. The report will be available in a few months.

In order that engineers and mechanics trained by the State shall, upon discharge from the Army, receive the positions for which they are fit, the University of California Alumni Association has established a Bureau of Occupations. The secretary is Homer Havermale, and his address is 201 California Hall, Berkeley.

THE METAL MARKET

METAL PRICES

San Francisco, May 27

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	16.50
Lead, pig, cents per pound	5½—6½
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce	$115
Quicksilver, per flask of 75 lb	$92
Spelter, cents per pound	7½
Zinc-dust, cents per pound	10—12

EASTERN METAL MARKET

(By wire from New York)

May 27.—Copper is quiet and easy. Lead is inactive but firm. Spelter is sluggish though steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May, 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

Silver production of the Nipissing mine at Cobalt last year was 4,117,389 oz making 52,915,197 oz. since 1904 The cost in 1918 was 39.02 cents per ounce.

The process that has heretofore been used in the treatment of the high-grade ore which gave satisfactory results for seven years, is an amalgamation process, using a large quantity of mercury. The price of this before the War was $33 to $39 per flask, but demand for war raised the price to $130. This so increased the cost of the process that it was decided to discontinue amalgamation and rely on cyaniding alone, after giving the ore a preliminary treatment with bleaching powder in the tube-mill. The necessary apparatus for this process was installed in the low-grade mill at a small cost, and in August the old high-grade mill was shut-down The new process is working smoothly and will be used as long as it shows a saving over amalgamation. The two plants treated during the year 430 tons of custom ore and bullion containing 1,668,350 oz., 938 tons of Nipissing ore assaying 1713 oz. per ton, and 513 tons of concentrate with an assay value of 1609 oz. per ton, making a total of 1926 tons containing 4,178,510 oz Of this the old high-grade mill treated 1102 tons, containing 2,733,407 oz., and the new plant 824 tons, containing 1,445,013 oz The refinery also handled precipitate from the low-grade mill containing 816,737 oz. The bullion shipped averaged 998 fine, and amounted to 190 tons containing 5,532,881 oz. Residue shipments were 2157 tons, assaying 9.03% cobalt. The demand for this material is good, at much higher prices than ever received before. The present price of cobalt is $2.50 to $3.50 per pound.

Cerro de Pasco, operating in Peru during 1918, realized $22,807,807 from the sale of copper, gold, and silver. Mining, smelting, refining, and administration cost $9,659,536. Dividends totaled $4,393,353. Current assets total $16,818,731; and liabilities $3,608,439. A new smelter is to be erected near Oroya.

Chile Copper Co. in the last quarter of 1918 produced 20,305,514 lb. from 996,695 tons of 1.64% ore. The recovery by leaching was 84.3%. The operating profit was $817,590.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

There is almost no inquiry or business in manganese-iron alloys and prices are nominally unchanged at $150 per ton, delivered, for standard ferro, and $33 to $35 per ton, furnace, for spiegel.

Eastern Metal Market

New York, May 21

All the markets carry a better and stronger tone, and prices are generally higher.

Antimony is stronger.

Copper buying has been extensive and prices have advanced.

Lead prices have been advanced and buying has been heavy.

Tin purchases for shipment from the East, when restrictions are removed, is the feature.

Zinc is quiet but firm and steady with prices higher, largely in sympathy with other metals.

ANTIMONY

The market is stronger, with Asiatic grades in wholesale lots for early delivery quoted at 7.75 to 7.87½c., New York, duty paid.

ALUMINUM

There is no change and No. 1 virgin metal, 98 to 99% pure, is quoted at 31 to 33c. per lb. in wholesale lots for early delivery.

COPPER

Buying has been active and expansive almost daily for the last six days, but the amount sold is conjecture. Some say that for May, sales will exceed 100,000,000 lb. As a result of these conditions prices have advanced, also almost daily, until yesterday electrolytic copper was quoted and sold at 16.50c., New York, for May-June delivery with some producers asking 16.62½c. For July, 16.75c. is asked and obtained, but as a rule there is much disinclination to sell beyond this delivery. Lake copper for May-June is held at 16.75 to 17c., with demand good. The entire market is strong and in firm hands. Little export demand has yet appeared, but what business has been done has gone at about ½c. per lb. higher than prevailing domestic prices. Production has been curtailed so that generally it is regarded as not more than 50% of capacity. The position of the producers generally is getting stronger and the market assuming a sellers' aspect.

IRON AND STEEL

The long-expected buying movement looked for as soon as price stabilizing was done away with has not appeared, although a measurable volume of business has developed. The conclusion is reached, however, from a survey of the position, that heavy buying cannot be delayed long. Concessions in prices are being made, but there is no general break. The most striking cut has been in steel plates for locomotives, but this involves a foreign order. A contract for 3000 tons has been split up among four companies at 2.50c., Pittsburgh, or $3 per ton below the domestic level. The Government has made no award of the 200,000 tons of rails recently inquired for, wide variations in quotations being reported. The leading interest is said to have named $45 on Bessemer and $47 on open-hearth rails, against four independent mills which are understood to have quoted higher, one as high as $55 and $57.

LEAD

Buying in lead was so large in volume late last week that the market was characterized by some to be almost booming or similar to the booming trade of months back. During the past week the American Smelting & Refining Co. advanced its price twice. On Friday, May 16, it raised its New York quotation from 5 to 5.10c. and on Monday, May 19, it pushed it to 5.25c., New York. Most of the buying referred to took place under the latter quotation, and it is stated that there has not been as much activity since the last lift in value. The outside market kept pace with the trust price. It is even stated that 5.30c., New York, had been done yesterday by outside sellers. In the last six or seven days or since the last report a large tonnage changed hands. In the opinion of one broker the lowest price for lead for some time has probably been seen, but he does not expect a decided expansion in prices.

TIN

This is the first time in many months that the tin market could be termed fairly active. In the latter part of last week a decided interest in future shipments from the Far East appeared, which resulted in sales in good volume for shipment as soon as restrictions are removed. The prices involved were from about 52 to 53.25c. per lb., an advance of 3c. per lb. over those realized for the small transactions in the week before last. If all sellers are taken into consideration it is stated that the total turnover in the last few days involves a fair tonnage, as the buying has extended into the present week. It is stated also that more tin could have been sold if more had been offered. Considerable English tin was also involved in the total movement at prices up to 52.50c. per lb. Buying has been more general than in a long time. The domestic price continues unchanged at the fixed level of 72.50c. for the allocated metal. There is no definite news as to when restrictions are to be removed, but July 1 is still generally expected as the approximate date. The London market continues strong and advancing, possibly on conditions supposed to exist when a free market in the United States obtains. Yesterday, spot Straits was quoted at £248 per ton, an advance of £8 in the week. In April, 3481 tons of tin arrived in England, but none in the United States.

ZINC

The zinc market seems to be the only one of the non-ferrous family that is not active, and yet quotations are a little higher. This is generally explained as due to the better tone in the other markets. At any rate prime Western for early delivery, May-June, is quoted today at 6.25c., St. Louis, or 6.60c., New York, with some small sales at this price. For July, 6.35c., St. Louis, is asked. The market is characterized as quiet, but strong and firm. Production has been curtailed somewhat in recent weeks, and some large producers are not operating at over 50% of capacity. Reports of considerable export business in the last few weeks are probably exaggerated, though there is some inquiry from England and there has been some little business done with Japan.

ORES

Antimony: High-grade ore is probably obtainable at 50 to 55c. per unit, Indian ore having already been offered at these levels. There is little demand and almost no sales.

Ferro-silicon: French 10 to 12% electric ferro is offered for American consumption at $77 French ports, which means over $100 per ton delivered in America. This contrasts with $45 to $55 per ton for the American product, and reveals the high cost conditions in France.

Molybdenum: Quotations range from 65 to 75c. per lb. of MoS_2 in 90% concentrates, with but little inquiry in evidence.

Tungsten: There is little activity or news. Prices are nominally unchanged at $7 to $10 per unit in 60% concentrates for high-grade ore. There are no developments in the ferro-tungsten market; prices are maintained as high as possible because of stocks of high-cost ores.

Company Reports

Reports of the companies at Tonopah, Nevada:

JIM BUTLER TONOPAH MINING CO.

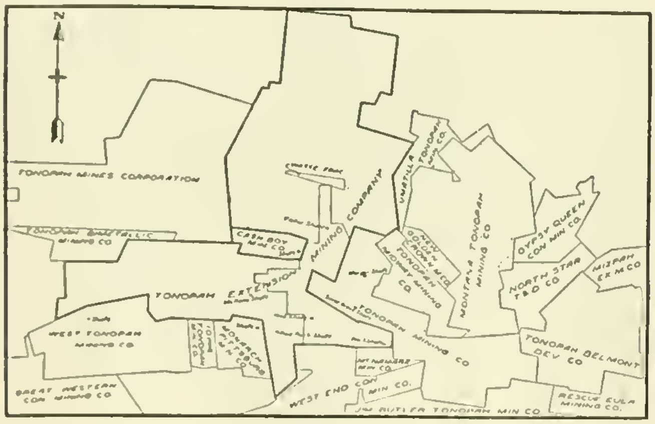
Property: mine at Tonopah, Nevada; also interest with the Tonopah Belmont in the Shawmut mine in California and Wagner mine in Colorado.

Operating Officials: Frederick Bradshaw, general superintendent; L. R. Robins, mining engineer.

Financial Statement: the period of the report is for 15 months ended December 31, 1918. The net profit was $296,525, a decrease of $187,151. Cash and call loan at September 30, 1917, amounted to $485,982, while after paying dividends, etc., the balance at the end of 1918 was $69,075.

Dividends: No. 6 and 7 absorbed $292,064, making $1,151,074 in 6 years.

Development: exploration has failed to expose new veins of importance, and ore-reserves have been so depleted that only a small tonnage remains. The West End-McNamara vein, in the company's Eureka and Sunset claims, contains considerable ore, and as it can only be worked through the West End company's openings, a lease agreement will probably be made. In the extra-lateral right litigation the matter was settled in favor of the West End.



PROPERTY MAP OF TONOPAH DISTRICT

Production: a comparison with previous years follows:

Year	Tons	Silver, oz.	Gold, oz.	Cost	Profit
1918	27,688	603,141	6,821	$13.61	$296,525
1917	40,297	1,017,746	11 617	11.94	483,675
1916	46,489	1,125,268	12,370	10.80	359,387
1915	48,533	1,282,042	14,593	10 40	335,622
1914	31,722	942,257	10,500	12.18	247,502
1913	19,181	468,325	4,959	....	102,682

TONOPAH BELMONT DEVELOPMENT CO.

Property: mines and mill at Tonopah, Nevada; also control of the Shawmut mine in California, Surf Inlet in British Columbia, and Wagner in Colorado, all gold producers, in which a total of $2,317,799 has been invested. The Surf Inlet has repaid in full all money lent it.

Operating Officials: Frederick Bradshaw, general manager; L. R. Robins, mine superintendent; Herman Dauth, mining engineer; A. H. Jones, superintendent of milling; and W. H. Royston, mill superintendent.

Financial Statement: the net profit during the 10 months ended December 31, 1918, was $557,984, about half of that of 1917. Available assets total $643,097, and current liabilities $170,165. The balance of undivided profits on February 28, 1918 was $2,149,843, and after adding the 1918 profits and deducting depletion charges and dividends the surplus is $1,838,892.

Dividends: No. 35 and 36 totaled $337,505, making with the $150,000 paid on April 1, 1919, a total of $9,818,063 since 1906.

Development: there was completed a total of 9263 ft., at a cost of $1.069 per ton milled. Some small new veins were opened, and reserves were increased thereby, the total of positive ore being calculated at 82,798 tons. The total cost of mining was $5.118 per ton, a gain of 7.5 cents.

Production: the plant at Millers was idle during the period. The plant at Tonopah treated 60,361 tons of custom ore, as well as 87,089 tons of Belmont ore. The custom treatment gave a profit of $14,374. Total milling charges were $3.134 per ton, an increase of 5.3 cents. A comparison with previous years follows:

Year	Tons	Silver, oz.	Gold, oz	Silver, oz	Gold, oz.	Cost per oz. silver, cents
1918	87,089	15.30	0 162	1,076 941	10,974	20.07
1917-'18 ...	130,991	15.88	0.162	1,946,757	10,953	20.62
1916-'17	145,024	....	....	2,629,465	27,831	14.92
1915-'16	161,972	19 60	0 196	2,968,564	31,112	16.23

TONOPAH EXTENSION MINING CO.

Property: mine and mill at Tonopah, Nevada.

Operating Officials: J. G. Kirchen, general manager, A. Case, general superintendent; J. L. Dynan, mine superintendent; E. M. Kirchen, mill superintendent; M. L. Davenport, purchasing agent.

Financial Statement: receipts last year (ended March 31, 1919) totaled $1,630,280, of which $515,509 was profit (more than double that in 1917), after deducting $104,366 for Federal taxes, and $44,886 for depreciation. Current assets at the end of 1918 were $2,393,421 in excess of liabilities.

Dividends: No. 23, 24, and 25 absorbed $192,407, making $1,912,399 to December 31, 1918.

Development and Mining: 3868 ft. of exploration was done at the No. 2 and 6454 ft. at the Victor shaft. Total workings measure 28.13 miles. At the former, the 1440-ft. level yielded most of the ore. Prospecting resulted in discovery of a number of good shoots, but chances for finding large orebodies are remote. At 1260 ft. a branch of the Murray vein yielded several thousand tons of unusually rich ore. At 1680 ft. in the Victor shaft, stopes on the Merger vein produced a large tonnage. The Murray vein ore-shoot is 600 ft. long, and from 3 to 30 ft. wide, of good grade. No definite calculations of reserves are possible. A new head-frame, Nordberg hoist, compressor, skips, ore-bins, and pumps are erected or are under erection at the Victor shaft.

Milling and Production: the mill treated 114,921 tons of ore, assaying 12.818 oz. of silver and 0.121 oz. of gold per ton, an increase of 1.047 oz. of the former and 0.004 oz. of the latter. Extraction was 93.05%, an increase of 2.54%, equal to 1,367,440 oz. of silver and 13,143 oz. of gold. Price for silver averaged $1.00944 per oz. The bullion realized $1,652,031, less $27,268 for freight and refining.

Costs totaled $9.562 per ton, a decrease of 26.9 cents. Mining accounted for $4.804, and milling $3.447 per ton.

TONOPAH MINING CO. OF NEVADA

Property: mines at Tonopah, mill at Millers, Nevada; and control of dredging property at Breckenridge, Colorado; copper mine in Manitoba, and gold mines in Nicaragua.

Operating Officials: W. H. Blackburn, general superintendent; H. W. Stotesbury, mine superintendent; H. A. Johnson, mill superintendent.

Financial Statement: the report for 1918 shows that net earnings were $782,062. The surplus of $3,862,884 at the end of 1917 was increased to $4,199,444.

Dividends: No. 50-53 totaled $375,000.

Development: 4619 ft. of exploration from three shafts failed to disclose any new orebodies. Raises and cross-cuts from various veins opened parallel shoots near the Mizpah and Silver Top shafts. On the Mizpah Fault vein, at 500 ft. depth, a considerable quantity of ore is now being stoped.

No definite estimate of reserves is possible. Old pillars and blocks below old drifts were profitably mined.

Production: the plant at Millers treated 1199 tons of $26.73 ore, and 102,404 tons of $5.29 ore-house reject, while the Belmont company's mill treated 53,279 tons of $18.34 ore. Total costs were $5.245 per ton, a slight decrease owing to less development being done.

Nicaraguan Properties: the Eden Mining Co.'s new mill started in November. The Tonopah Nicaragua Company's property shows by drilling 1,182,088 tons of ore, averaging $0.91 gold, and 5.059% copper. A reduction plant is contemplated.

WEST END CONSOLIDATED MINING CO.

Property: mines and mill at Tonopah, Nevada; also property in Honduras, Central America; and at Searles Lake, California.

Operating Officials: J. W. Sherwin, general manager; H. D. Budelman, mine superintendent; W. D. Jenkin, mine foreman; F. C. Ninnis, mill superintendent.

Financial Statement: the revenue during 1918 totaled $2,030,897, including $1,478,488 from company and custom metals extracted, $68,017 from sundries, and approximately $316,375 from the money held in escrow during the dispute with the Jim Butler company. Expenses totaled $1,466,949. The cash balance, after paying dividends, is $253,907, against $47,656 at the end of 1917.

Dividends: $357,697, making a total of $1,073,092.

Development and Mining: the total of exploration was 7214 ft., costing $10.30 per foot for drifts, $9.70 for raises, $10.16 for cross-cuts, and $25.13 for winzes; while the cost per ton was $1.57, an increase of 12 cents. Work was continued aggressively in the West End section of the property, and while the orebodies cannot be measured satisfactorily, the future is very favorable. In the Ohio section, reserves are now 82,000 tons, nearly double those of a year ago, and with a gross value of over $2,000,000. Out of 2430 ft. of driving on the Ohio vein, 1410 ft. was in pay-ore, and of 225 ft. of raising, 198 ft. was in good ore. The cost of mining was $6.74 per ton, an increase of 69 cents. The direct proportion of this was $5.84 per ton.

Production: company ore treated amounted to 50,195 tons, assaying $19.73 per ton. The metal content was 835,252 oz. of silver-gold bullion, of which 91.97% was extracted at a cost of $3.33 per ton, a rise of 6 cents. Custom ore treated was 16,323 tons.

MODDERFONTEIN B. GOLD MINES, LIMITED

Property: mine and mill in the Far East Rand, Transvaal.

Operating Officials: C. L. Butlin, manager.

Financial Statement: revenue from gold last year was £1,254,053 ($6,081,000), of which £658,587 ($3,196,000) was profit. Taxes amounted to £117,130 ($567,000). After paying dividends, the balance forward to 1919 was £198,645 ($960,000).

Dividends: No. 12 of 42½% and No. 13 of 40% absorbed £577,500 ($2,798,000), making £3,027,500 ($14,683,000) to date.

Development and Mining: exploration amounted to 9894 ft. Of this footage, 62% was in pay-ore. The re-measured ore-reserves total 3,378,000 tons, averaging 9.2 dwt. across 62 in. This is a decrease of 150,000 tons. Of the total, 45% averages 12.7 dwt. per ton. To serve the deep sections of the mine a 20-ft. circular shaft is to be sunk.

Milling and Production: after sorting out 15% of the ore mined as waste, the 100 stamps and 7 tube-mills crushed 605,500 tons of ore. The stamp-duty was 17.2 tons per day. The ore contained 10.269 dwt. per ton. By amalgamation and cyanidation there was extracted 96.9%, equal to 301,278 oz. of fine gold.

Costs totaled 19s. 8d. ($4.72) per ton, an increase of 3d. (6 cents).

The mine is now equal to a monthly output of 60,000 tons of ore. A new 65-drill air compressor is to be erected.

CALUMET & ARIZONA MINING CO.

Property: mines at Bisbee and smelter at Douglas, Arizona.

Operating Officials: J. C. Greenway, general manager; W. B. Gohring, superintendent of mines; H. A. Clark, superintendent of reduction works; W. E. McKee, superintendent of machinery.

Financial Statement: the total revenue during 1918 was $15,528,530. Operations and taxes ($1,398,391) amounted to $9,905,176. Current assets total $16,443,220 and liabilities $2,086,881.

Dividends: No. 57-60 absorbed $5,140,062, making $41,132,824 to date.

Development: including 16,281 ft. of diamond drilling, there was 99,355 ft. of work accomplished at the Briggs, Cole, Junction, and Oliver shafts. The Junction pumps lifted 1,664,518,511 gal. of water, a decrease of 100,000,000 gal. This shaft used 2,476,175,380 ft. of air, and the Oliver 952,189,000 ft. Reserves were increased somewhat. The output was 676,888 tons of dry ore. High sulphur-low copper ore sold to various smelters in Arizona totaled 98,948 tons, manganese ore to steel-makers 5793 tons, lead-zinc ore to paint-makers 254 tons, and 79 tons of lead ore to the smelter at El Paso.

At the Gadsen copper mine at Jerome, the shaft was sunk to 1230 ft. A cross-cut is now out 1100 ft. to find the Jerome fault, estimated to be from 1300 to 1600 ft. west on the 1200-ft. level.

Production: the reduction works handled the following

	Roasters	Reverberatories	Blast-furnaces	Converters
Number working	18.1	4	2	
Days	...	294.1, 337.0, 353.3, 314.7	335.3, 40.0	...
Charge, tons	556,001	602,272	313,095	52,015
Blister copper output, tons	....	......		42,088

The roasters reduced the sulphur contents from 27.7 to 9.7%. The acid plant made 67,110 tons of 60 sulphuric, an increase of 16,885 tons.

OLD DOMINION COMPANY

Property: mines, mill and smelter at Globe, Arizona.

Financial Statement: sales of gold, silver, and copper in 1918 realized $5,731,082. Operations, plus $216,080 for taxes, totaled $5,125,125. Current assets are $3,307,336, and liabilities $2,677,768. With the balance of $4,974,324 from 1917, there was available $5,276,086. After paying dividends, the balance for 1919 was $4,087,802.

Dividends: No. 41-44 totaled $1,188,284, making $14,405,260 since 1905.

Development: this covered 22,163 ft., a decrease of 2158 ft. On account of water, the A shaft was only sunk 5 ft., but when the electric centrifugal sinking-pump is put in sinking will be continued. Exploration on the No. 17 and 18 levels east was particularly encouraging, especially as the copper content persists. Results in the smelting ore-zone between No. 18 and 16 west have been disappointing for two years. The east side orebody produced most of the concentrating ore in 1918. The mine-pumps lifted an average of 3,730,000 gal. of water per 24 hours.

Production: ore of all classes totaled 230,451 tons, averaging 4.52% copper, compared with 199,888 tons and 4.97% in 1917. The metal output was 33,378,158 lb. of copper, 184,982 oz. of silver, and 5071 oz. of gold. Of the copper, 21,896,780 lb. was sold at 25.01 cents per pound.

Book Reviews

Chemical Calculations. By R. H. Ashley. Second edition, revised. Pp. 276, ill., index. D. Van Nostrand Co., New York, 1918. For sale by 'Mining and Scientific Press'. Price, $2.

We had just been reading a paper by P. A. Dean on chemical equations in the April Journal of Engineering of the University of Colorado when this new book came to hand. A beginner in chemistry may experience difficulty in writing chemical equations, even may advanced students, and the same might be said about chemical calculations. In order to solve any chemical equation or calculation, the formula for the reacting substances and the products formed must be known, the valence of the reacting substances, the direction and amount of the change of valence, and the atomic weights of the elements. The decomposition of mercuric oxide is a simple example. For instance, it is required to find the number of grams of oxygen that will be liberated by the decomposition of 1.7000 grams of mercuric oxide. The equation and calculation is:

$$2HgO = 2Hg + O_2$$

$$2(216.6) = 2(200.0) + 2(16)$$

and $\frac{2(16)}{2(216.6)} \times 1.7000 = 0.1256$ gram of O yielded by 1.7000 grams of HgO. In chemical calculations, ratios, approximate numbers, and interpolation should be thoroughly understood. Chapters 4 to 10 inclusive, give explanations, laws, and problems worked out on heat, specific gravity, gas, atomic weights, and gravimetric and volumetric analyses. There are 515 problems in all, with answers. An example in gas calculations is, calculate the composition of a gaseous mixture of carbon monoxide and acetylene, the volume of the mixture taken being 20 cc., the volume of oxygen added 50 cc., the volume of explosion 52 cc., and volume of oxygen left after KOH treatment 24 cc. The answer is 8 cc. of C_2H_2 and 12 cc. of CO. In acid calculations this one is typical: calculate the weight of 50° Baumé sulphuric acid equivalent to a shipment of 2160.61 cu. ft., measured at 120 F., a sample of which showed 56.14°B. at 80°F. The answer is 252,410 lb. We feel sure that metallurgical chemists will find this work of great aid in their calculations.

Quantitative Analysis. By E. G. Mahin. Second edition. Pp. 605, ill., index. McGraw-Hill Book Co., New York, 1919 For sale by 'Mining and Scientific Press'. Price, $3.50.

There were four impressions of the first edition of this work, and judging by the present one, which is 100 pages larger than the first, and has been revised, we would say that it fulfills its object in being a reference for students and semi-advanced chemists. In the book before us, improvements consist of bringing standard methods of analyses of industrial materials up to date, addition of analyses of certain alloy-steels, and soft-bearing metals, the re-writing of the discussion on metallography and treatment of steel, and a new system of chapter heading, particularly under the general caption of industrial products and raw materials. One of the outstanding features of Mahin are the excellent instructions on general principles and use of laboratory apparatus, whenever a new subject is started and the method is described. This is especially so in 72 pages, the chapter on gravimetric analysis. In the chapter on experimental gravimetric analysis will be found the determination of the chloride, sulphate, and phosphate radicals, and the chlorides, bromides and iodides of silver. In electro-analysis, it must be remembered that the principal reasons for failure to attain accuracy are (1) deposition may not occur upon passage of a current; (2) the deposit may be contaminated by other products of electrolysis; and (3) the deposit may not have the proper physical character so that it will not adhere to the electrode but crumbles off during electrolysis or washing. These factors are discussed. The short chapters on indicators and standardization of solutions are instructive in their conciseness; and that on oxidation and reduction fully explains these reactions. The 280 pages covering the analysis of industrial products and raw materials are divided into chapters dealing with rock analysis, fuels, oils, water, steels and alloys, and agricultural materials. Photo-micrographs show the structure of various steels. Students desiring a knowledge of the fundamentals of the fire-assay will find 20 pages on the subject.

Chemical Analyses of Rocks. By H. S. Washington. Third edition, revised and enlarged. Pp. 271, index. John Wiley & Sons, New York, 1919. For sale by 'Mining and Scientific Press'. Price, $2.50.

Briefly, this volume contains a selection of methods for the chemical analysis of silicate rocks, especially those of igneous origin. In the study of rocks and ore formations, petrological and chemical analysis are most essential; many mines have been unjustly condemned on account of their being no such investigation made. The main constituents of most rocks are SiO_2, Al_2O_3, Fe_2O_3, FeO, MgO, CaO, Na_2O, K_2O, and H_2O; these must be determined in every rock analysis. Of the minor constituents, TiO_2 and P_2O_5 are the most important, and should be determined also, otherwise they will affect the final results. When in the field, a sample of rock must be representative of the mass being examined, just as in sampling ore. After discussing the apparatus and reagents used in the laboratory, and the mode of operation, the methods are then described, including solution, separation, precipitation, ignition, and probable errors. The last four pages give detailed calculations in the analyses of a gray porphyritic basaltic lava from Mt. Etna, wherefor the reason for a peculiar looking frontispiece from an old woodcut. We think that the author could have easily selected some other rock masses for analysis and a good photograph to accompany it. Otherwise, the work is instructive, and the sequence of investigation continuous from sampling to reporting the result.

Broaches and Broaching. By Ethan Viall. Pp. 216, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, $2.

The author defines broaching as "the working out of holes or slots, or the machining of surfaces, by tools having a number of successive cutting teeth of increasing size, no matter whether these teeth are arranged singly or in multiple." The book discusses the special field and advantages of broaching work. The chapter-headings are: Broaching and Broaching Tools; Standard Types of Broaching Machines; Examples of Pull-Broaching Work and Practice; Examples of Push-Broaching Work and Practice; The Design of Pull-Broaches; The Design of Push-Broaches; Making Broaches. The book is well-illustrated with photographs of machines and of work done on them. It will be of value to machinists generally.

Analysis of Statistically Indeterminate Structures by the Slope Deflection Method. By W. M. Wishon, F. E. Richart, and Camillo Weiss. Bulletin 108 of the Engineering Experiment Station, University of Illinois, Urbana, 1918. Pp 214, illustrated.

The investigation was made to obtain a convenient method of analyzing the moments, stresses, and deflections for a number of typical structures. The explanations are in sufficient detail to enable a designing engineer to use them in his problems.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

WATER-WHEELS FOR BRAKING AND INITIAL POWER

A unique use of water-wheels has been made in Plumas county, California, by the Spanish Peak Lumber Co. The equipment is on the company's timber lands, where water-power is available but access to the railroads is impossible. Two Pelton water-motors, set in opposition, have been adapted to an aerial tram control to furnish primary power and braking effort for the cableway.

The tram is essentially a gravity system, but due to the difference in elevation of loading and discharge-stations, power is required for braking when loaded carriages are hung on the cable. Power is also required for driving the haulage cable when unloaded. The tram has a total length of 27,200 ft., crossing a ridge of 4900-ft. elevation between the loading-station at the sawmill and the discharge-station at the railroad. The latter station is 890 ft. lower than the former, and a braking effort to absorb a maximum excess of 12 hp. is necessary when the cable is fully loaded. The system requires a torque of 20 hp. when the cable is not loaded.

Type of Aerial Tram and Characteristic Country

Two 24-in. Pelton wheels, rigidly connected in opposition through a solid coupling, make up the driving and braking unit. They are controlled by a needle nozzle, actuated by oil governors, in regulating the cable speed, the regulation being to hold speed constant. The governors are so adjusted that when the cable slows below normal speed, due to a light load, water is admitted to the driving motor, and power is generated to maintain the normal speed. When the cable is loaded, speed tends to increase, and water is shut off the driving motors and admitted to the braking motor. The impact of the buckets of this wheel rotating against the jet develops the requisite braking effect and the speed is held at normal.

Water for this system is taken from an old mining ditch above the mill, with an effective head of 230 ft. Several smaller wheels are driven by water from the same supply, for driving small machines in the mill. Electricity for lighting the mill and other buildings is generated by a 15-kw. alternator, belt-driven from the flywheel of the cable-control unit. Fire protection is also provided by water from the ditch.

The handling costs for the cableway have been well under the contractor's guarantee of $2.40 per M board feet, and operation has been so successful that the companies' entire stand of 200,000,000 ft. will be moved to the railroad at lower than that figure.

The Driving and Braking Water-Wheels

NEW TYPE OF STEAM ENGINE

The distinguished position that B. V. Nordberg has attained as a designer of steam engines lends special interest to the announcement by the **Nordberg Manufacturing Co.** of Milwaukee, Wisconsin, of a new type of Uniflow poppet-valve engine. The Nordberg company was the first to develop Uniflow engines in this country, and the advantages of this type in maintaining high economy at underloads and overloads is well known. The new Nordberg-Todd uniflow engine is built in sizes ranging from 200 to 2000 hp. for any available superheat, any available steam pressure, any available vacuum, and any available back pressure. The assertion is made that under any of these conditions these engines will operate with lower steam consumption per horsepower, over wider variations of load, than any steam prime-mover thus far developed. Of special interest is the fact that the engine can be changed from condensing to non-condensing operation, or the reverse, while running.

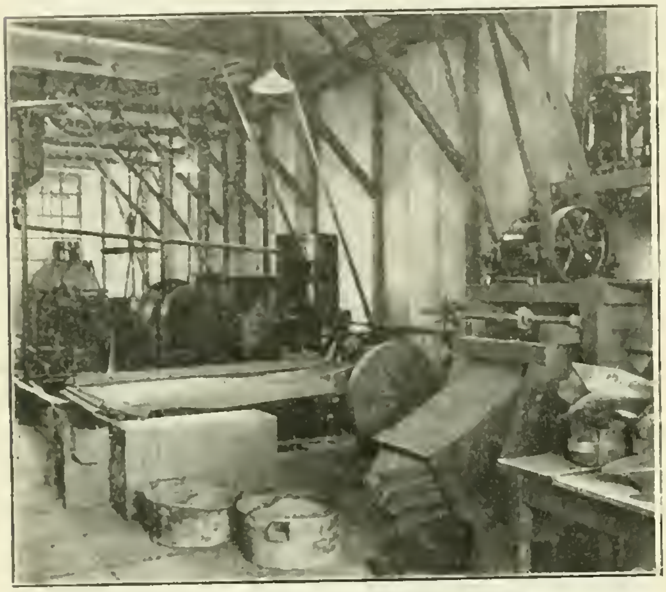
The Advance Machinery & Supply Co. of Denver, which is Western representative for the De Laval Steam Turbine Co., C. H. Wheeler, Uehling Instrument Co., Republic Flow Meters Co., Ohio Blower Co., Richardson-Phenix Co., Betson

Plastic Fire Brick Co., Heiney Chimney Co., Viking Pump Co., Yarnall-Waring Co., etc., announces that S. A. Koenig, first lieutenant in the Coast Artillery, has been discharged and joined the Advance company at Denver as sales manager.

A NEW ORE-TESTING PLANT

Since Sill and Sill of Los Angeles moved their plant and office to 1011 South Figueroa street, and added a great deal of new equipment, they now have a complete ore-testing works for both large lots and preliminary tests.

For concentration there is a gyratory crusher, a set of rolls, and shaking screens, for screening products, or an Overstrom hydraulic classifier where a hydraulically classified product is desired as a feed to the 6-ft. Wilfley table. For crushing there is a 4-ft. Abbe tube-mill for cyanide, amalgamation, or flotation tests. The tube discharges to a pump, which raises the pulp to the distributing cone, where it is fed to a 3-ft. K & K oil flotation machine, or to the 4-ft. Senn batea amalgamator, or to the pachuca tanks, or the electro-cyanide-chlorination tank. This makes it possible to duplicate actual working conditions. For the final treatment of the pulp, from the pachuca tanks, or electro-cyanide, or flotation, there was added recently to the above equipment a 4-ft. single-leaf 32 sq. ft. area, American filter.



Interior View of Part of Testing Plant

COMMERCIAL PARAGRAPHS

In an 8-page leaflet, the **Western Wheeled Scraper Co.** of Aurora, Illinois, shows its road-builder's dump-car, truck, service-car, track and switches; while useful diagrams illustrate the placing of industrial track and daily capacity of any given job.

The firm of **Collins & Webb**, Los Angeles, Cal., has opened a branch office at Tonopah, Nevada. D. W. Janney is the man in charge. A stock of compressors, motors, receivers, tanks, etc., will be carried in the warehouse there for immediate delivery.

The uses of the different kinds of Oronite paints are very varied, according to the **Standard Oil Co.** of California. Wherever a protective coating is needed—on metal, wood, brick, or concrete—everywhere conditions may be severe, these paints have shown their high quality and economy.

The **Norwalk Iron Works Co.**, South Norwalk, Connecticut, recently issued a new bulletin on Norwalk air and gas compressors. It is attractively prepared, and gives specifications and descriptions of the entire line of compressors for all purposes of mining and metallurgy.

The United Filters Corporation, 65 Broadway, New York, announces the appointment of C. B. Oliver as manager of its Chicago office in the Peoples Gas Building. He has been identified with the company for several years, and has a wide and successful experience as a filtration engineer.

The Beckman & Linden Engineering Corporation is erecting a 100-kw. electric furnace in its research laboratories at 41 Minna street, San Francisco. This furnace is to be used for making investigations in the electric smelting of all kinds of ores for clients. The firm, within the near future, is to start an investigation of a nickel-copper ore, which, it is believed, can be reduced in the electric furnace, and a metal similar to Monel metal produced. This plant is the only one of its kind west of Niagara Falls. There are a number of problems in ore treatment that could be solved by the use of the electric furnace.

The Smooth-On Manufacturing Co. of Jersey City, New Jersey, has just issued a new and revised edition of 'Smooth-On Instruction Book No. 16'. This, like its predecessors, is made up of helpful and interesting descriptions of engine and boiler-room repairs of all kinds. These are described by the men who made them in such a way that similar problems can be quickly and economically solved by other engineers. The book is well illustrated by actual photographs and drawings. Among the subjects covered are engine repairs, pump repairs, boiler and tank repairs, pipe-line, maintenance, valve repairs, wheel pit and engine bed construction, etc. A copy of the book will be mailed free on request to the company.

The E. I. Du Pont de Nemours & Co., in discussing coverings for concentration tables, state that linoleum has generally been used for this purpose, but has not been entirely satisfactory because the cyanide solution used blisters it, thus making its life short. Recently a new material has been successfully tried, especially in gold recovery. It is a cotton-base fabric having a pyroxylin coating. It is thinner and decidedly more pliable than linoleum, but is as waterproof as rubber. The Portland mill at Victor, Colorado, has operated one of its tables, covered with this material, continuously for a year without change. It showed no blistering and little deterioration otherwise. The material was designed originally to be used for automobile and furniture upholstering—it is a leather substitute, in fact. Thomas B. Crow, of the Portland mill, and Luther Lennox, assistant, invite mining and concentrator men interested in this subject to write them for any additional information desired.

The American Malleable Castings Association of 1900 Euclid building, Cleveland, Ohio, through G. P. Blackiston, director of publicity, announces that at last an authentic treatise on malleable iron has been written, published, and is issued gratuitously by this Association. Although great progress has been made in this particular industry the last few years, little or no progress has been made in keeping the public informed regarding such activities. In fact there is but one book available at present treating on malleable iron, but it is so many years out of date that it is of little value. The latest booklet—'Malleable Iron'—although but a forerunner for a comprehensive volume to be issued later by the Association, is filled with valuable data. It is divided into three parts: I—What is Malleable Iron. II—The American Malleable Castings Association. III—The Use of the Malleable Iron Casting; Can Heavy Sections of Malleable Iron be Completely Annealed?; The Skin of a Malleable-Iron Casting; Malleable-Iron Castings Resist Rust. A copy of this book will be sent to anyone mentioning this paper if they address the Association at Cleveland, Ohio.

AS we go to press we hear that the Supreme Court's decision in the flotation case is against the Butte & Superior company in that it gives Minerals Separation patent rights to the use of oil up to 1%. We expect to publish the text of the decision in our next issue. This is a severe blow to the mining industry of the United States.

IN this issue we publish a timely article on the recovery of copper from flotation concentrate by leaching. It is written by Mr. Percy R. Middleton, now at Salt Lake City, but recently arrived from Australia, where he studied the subject in a practical way by means of experimentation on a working scale, notably at Mount Lyell. We know that what he says will be found interesting by those engaged in flotation and we hope that some of our readers will describe some of their own efforts to apply leaching to the products of flotation. By such exchange of ideas we may hope to conquer this metallurgic problem, which is one of the most insistent of the present day.

WE understand that the War Minerals Relief Commission has been unable to make extensive plans for a systematic examination of claims until recently on account of the irregularity with which the claims have been presented and the fact that many of them were forwarded without the questionnaire, which had to be completed before the claim could be considered as filed. On April 30, however, the Commission authorized general examinations in California and Oregon, and on May 17 gave a similar authorization to cover the rest of the United States. A corps of engineers and auditors is already in the field, including four engineers on the Pacific Coast, three of whom were with the Bureau of Mines during the War.

OIL of good quality and in considerable quantity has been struck in England for the first time. The discovery is due to the initiative of Lord Cowdray, formerly known as an engineer by his name of Sir Weetman Pearson. He built the Tehuantepec railroad across Mexico and is now identified with big oil interests in the Tampico field. On May 27 at a depth of 3000 feet in Derbyshire a well was 'brought in', the oil rising in the bore to 400 feet. This work, which is being backed by the British government, is the direct result of geologic deductions, supplemented by experience on other oil-fields. It is a highly interesting development, largely because it represents the application of scientific reasoning to industrial enterprise.

OUR country is prospering exceedingly. During April our exports had a total value of 715 million dollars and our imports 273 millions, leaving a balance of 442 millions. It is noteworthy that the so-called balance of trade in April was equal to the net aggregate balance accumulated in the same month of the 17 years prior to 1915. The annual average of exports in the ten years from 1904 to 1913 was only 147 million dollars, the imports 119 millions, and the difference 28 millions. During the first quarter of 1919 we have sold abroad products worth $2,350,000,000, which is more than was exported in any whole year prior to the War. That is why foreign exchange is so weak and the dollar so strong.

E. S. MARTIN has made 'Life' much more than a fountain of humor during recent years; he has made it a foremost organ of opinion. His editorial writings have made 'Life' influential during the War. In a recent issue, speaking of Germany's plight, he says: "The real thing for her to lament is not the loss of colonies or ships, or the Saar coal, or Danzig, but her loss of character." By losing the War she escaped, he says, "the complete spiritual downfall that would have come with victory." As The Book says: "What shall it profit a man if he gain the whole world and lose his own soul." Germany pawned her soul with the Devil for the sake of loot and the fiend gave her a Dead Sea apple, and the taste of Sodom is bitter.

PRESIDENT WILSON struck the right note in his Memorial Day address at the American cemetery of Suresnes. Although the number of our dead in France is small as compared with those of the Allies, the number seems more than big enough to those of us whose kinsmen are counted on the roll of honor. The sacrifice they made must not be in vain. Most of them went overseas because their country called upon them to go, and having accepted the duty they were determined to perform it up to the hilt, with the confident expectation of defeating the Germans and returning home as soon as the task was done. The false heroics that have been read into their fine performance only tend to belittle it. They attended to the matter in hand without bothering about the larger aspects of the question. But whether they foresaw the purpose of their deeds or only rejoiced in the opportunity of service for their flag, it is certain that they turned a page of history and saved civilization from a supreme outrage. "It is our privilege and our high duty to consecrate ourselves afresh on a day like this to the objects for which they fought." The President's words will find an echo in our hearts. Moreover, he is right in saying that these men will have died in vain if the result is not to make impossible another such war. The millions of dead on the battlefields of Europe and the thousands, many of them women and children, on the dark floor of the sea call upon the living to see to it that there shall never again be a war like this one from which we are now emerging. Whatever their politics or creed, the plain people of this country, as of every other civilized country, welcome any sincere effort to establish peace, and therefore will be willing to give a fair trial to the Covenant of the League of Nations.

HERBERT CASSON, in the 'Boston News Bureau,' tells us that the British are sick of bureaucracy, "the gigantic system of Government departments that was made necessary by the War: and which is now digging itself in and trying to become permanent." The "and which" is regrettable, but the interest of the statement survives. He adds: "The business man, like the soldier, has been carrying a heavy kit, and now he wants to throw it off," but officialdom is unwilling to free him from the burden. We in this country may not have been as tightly bound with red tape, but it must be confessed that to us also the halo-hatted control of our amateurs in Washington is becoming irksome. War is destructive, business is constructive. Mr. George Creel and his press bureau, Mr. Bernard Baruch and his metals bureau, Mr. Harry Garfield and his coal bureau, together with a few others might be permitted to return to private life, with thanks.

CONDITIONS in Mexico have again reached the boiling-point. Carranza's government is menaced by revolt in many parts of the country, especially in the North, where Pancho Villa and Felipe Angeles have joined hands, with the support apparently of other subversive elements identified with Felix Diaz, Vasco Gomez, and Eulalio Gutierrez. It is said that a dozen distinct revolutionary movements are afoot in Mexico, ranging from mere banditry to real political protest. The *de facto* government of Carranza, having failed to raise a loan in New York, is in a bankrupt position and finds difficulty in placing any sort of army in the field. The request for permission to transport Carranza's troops across Texas, New Mexico, and Arizona was granted by two of the State governments but refused by Governor Hobby of Texas, because it might incite reprisals against Americans exposed to Villa's savagery. Some outrages have been committed recently and the position of Americans in northern Mexico is jeopardized for the moment. General Felipe Angeles is a man of education and unusual intelligence; he won distinction as an artillery officer in the Mexican revolution, and during the European war he represented the French government as inspector of munitions purchased in the United States. We understand that he is a graduate of the French school of artillery at Saint Cyr. It is said that he is held in high esteem by the French and that at the time of the Niagara Falls conference with the South American representatives in 1915 he was considered the best man for the Mexican presidency. His association with Villa, however, is against him. It may be necessary for conditions in Mexico to become worse before they become better. The present disorder is confined largely to the northern territory; on the west coast conditions are normal.

COSTS of producing copper appear to be declining from their war-time maximum, for the Utah Copper Company's latest quarterly report shows a cost of 13.72 cents per pound, as compared with 16.42 in the previous quarter; concurrently the Nevada Consolidated records a decrease from 19.01 in the preceding quarter to 16.85 cents per pound in the first quarter of this year. At the Ray the reduction has been even larger, from 19.3 to 15.1 cents, while at the Chino, with a 15c. cost, only 0.8 cent has been lopped off during the quarter. The fortunes of these big copper mines have been seriously affected by the drop in the price, as might readily be imagined. From a surplus of $1,248,786 on September 30 the Utah Copper has come down to a deficit on March 31, after paying its dividend, of $1,955,410. The four mines mentioned show an aggregate deficit of $4,583,178, as compared with an aggregate surplus of $574,721 six months earlier. During the first four months of 1919 the dividends paid by the copper mines of this country totaled $25,048,986, as compared with $53,252,471 two years ago.

RECOGNITION of Admiral Kolchak's *de facto* government in Siberia was anticipated by us in our issue of April 26. It is reported that the Council of Four at Paris has decided to recognize the anti-Bolshevik regimes of Admiral Kolchak and General Denikine on condition that they agree to convoke a genuine constitutional assembly and accept its verdict in determining the form of government to be established. This item of news is important to the mining profession because it warrants the anticipation that law and order will be established in Siberia, where are several important mines in which American mining engineers are interested as consulting engineers and managers. If once political stability is restored in that vast mineral region it may be expected that new enterprises will be set afoot Alexander Vassilievich Kolchak [sometimes spelled Koltchak] came into power on November 12, 1918, when a group of officers, representing the Constitutional Democratic party in Russia, arrested the Social-Revolutionist members of the so-called Constituent Assembly, a loose aggregation of political units, while in session at Ufa, in the Ural province. These followers of the Admiral of the Black Sea Fleet even seized the president of the Assembly, Nicolai Avksentieff, and put him in prison together with a large part of the Assembly. By thi *coup d'état* Admiral Kolchak sprang to power and became the leader of the anti-Bolshevik forces in Siberia

He won the support of the moderate parties and has established a strong administration at Omsk

Prospecting in Canada

A short time ago we published an interview with Mr. Horace V. Winchell, a representative of the best type of American mining geologist; in this issue we give a similar interview with an equally worthy exponent of Canadian economic geology. Mr. Willet G. Miller is a stalwart Anglo-Celt, a big man physically and in character, a scion of the Viking breed, which has explored the far corners of the earth and carried the miner's pick in the vanguard of civilization. He is usually called Dr. Miller by reason of a double scholastic accolade, for he is a Doctor of Laws of Queen's University, where he taught, and also of Toronto University, his alma mater. He is one of those fortunate men whose services to the commonwealth have been recognized while they are still in the vigor of their manhood. Born in Canada of native-born parents, he typifies the traditions of a nation whose spirit was expressed with immortal eloquence during the War for Civilization. The interview tells the story of his life in a modest way. He would have said little if the interviewer had not cross-examined him with friendly persistence. His father had the tastes of a naturalist and from him he inherited the powers of observation which by academic training were developed into scientific research. While a student at college he early became a teacher also, the learning and the teaching being complementary and thereby fulfilling the true meaning of the word education—the drawing out of the mental faculties. His has been a fortunate career; early appreciated by his countrymen, he received an appointment, that of Provincial Geologist, for which he was well equipped, and then, by good luck, he had the chance of taking part in a mineral development of historic significance and industrial importance. Cobalt and Miller are names forever linked in honorable association. He appreciated the value of the discovery made in the course of cutting the grade for a railroad near Haileybury, in Ontario, and published a description of it almost immediately. The present writer, while editor of the 'Engineering & Mining Journal,' had the pleasure of printing that first account of the discovery at Cobalt in the issue of December 10, 1903. Although a cautious man—a trait inherited from his Scottish ancestors—Dr. Miller did not allow his scientific judgment to be stifled; on the contrary, he came out boldly with the statement that "the ore is very rich, containing values in nickel, cobalt, silver, and arsenic; and a comparatively small vein could be worked at a handsome profit." In the 15 years since then Cobalt has produced 300 million ounces of silver. Dr. Miller has been amply justified in his forecast. He did more than that; he gave the miners in the Cobalt district a large measure of timely and practical geologic information; he did not wait until the mines were nearly worked out and then prepare a beautifully worded obituary notice or a highly scientific autopsy; he distributed technical data while he was collecting them in his official capacity and thereby gave to the exploration of the ore deposits an intelligent direction that ensured success. During the Cobalt boom, with its orgy of mine promotion and stock speculation, he did not lose his head nor endanger his integrity. While others became millionaires by following the advice he gave officially, he remained true to his duty. He might have enriched himself greatly, for he received many tempting offers to resign his appointment and accept both handsome retainers and profitable participation in attractive enterprises. It was all to no purpose, he loved his work and stuck to his post. His classification of the Cobalt rocks still holds good. From the start he expressed a preference for the silver veins in the conglomerate as distinguished from those in the schist and diabase; he also predicted that in passing from the Huronian conglomerate into the Keewatin schist the veins would probably become impoverished. These opinions have been confirmed by mining. Therefore our readers will note with keen interest his references to the unprospected regions of Canada. We publish a map in order to give additional point to his important statement. Experience, in Ontario particularly, has shown that the pre-Cambrian rocks constitute a terrain favorable to deposits not only of the precious metals but also of copper and nickel. There is an enormous area of such rocks in Canada, particularly in the north and north-east. We desire to draw special attention to Dr. Miller's observations concerning the Hudson's Bay territory, which will be rendered accessible shortly by means of the railroad now under construction from the main line of the Canadian Pacific railway to Port Nelson. In these spacious sub-Arctic regions there remains, as Dr. Miller says, the most attractive unprospected area in the world. It is comparatively free from brush or forest and therefore open to exploration. We shall publish further information on the subject at an early date. At present the Sudbury ore deposits dominate the nickel market, but the chance exists that somewhere in this pre-Cambrian shield of the North there may be found other nickel lodes of comparable richness. The part that the Canadian nickel resources played in the War is well known, and it is noteworthy that Dr. Miller was foremost in organizing those resources for the use of the Allies. He gives expression to the international goodwill now sealed by comradeship in arms; indeed the unfortified boundary separating Canada from the United States is an outward and visible sign of a peaceful policy more eloquent than any Hague convention or Paris conference. If the rest of the world were as amiably disposed as the members of the mining profession in the two English-speaking countries of North America there would be no anxiety as to the maintenance of international amity. They are exchanging knowledge and co-operating in beneficent industry with the most hearty accord, and in this respect such engineers as Dr. Miller and Mr. Winchell are typical. The joint committee appointed recently by the Canadian and American mining institutes should serve further to promote good feeling, by taking prompt steps to remove any minor points of disagreement arising more particularly from the barbed-wire entanglements of tariffs and custom laws. One thing is sure, any American engineer going to Ontario will find Dr. Miller, Mr. Thomas W. Gibson, Mr. Reginald W. Brock, and other men of their kind, only too glad to welcome them and to express their welcome by giving all the geologic information available. They may find the tall Doctor a bit reserved and non-commital at first, but when the crust of reserve has melted, they will find an inextinguishable warmth coming from a heart as big as his broad chest. Fertile in ideas, capable of wide generalizations, a good judge of human nature, shrewd but kindly, they will find a man neither easily deceived nor ever willing to deceive. His long legs are as much at home in the primeval bush as they are under the thwarts of a canoe; whether in the field or in the council-chamber, he is a born leader of men; and one whose leadership is accepted gladly. Alike as chief of an exploring party in the wilderness and as president of the Canadian Mining Institute in the city, he has won the confidence and affection of his fellows. Sentiment he has and the sense of humor, but most of all a willingness to help others. That characteristic has been evident throughout his life in Ontario, whether as student or teacher, geologist or official. He has trained a number of young men now honorably prominent in Canadian geology; he started them on careers of acknowledged usefulness. Honors have come to him, academic and professional, but no honor counts so greatly as the affectionate regard of the young men to whom he has given a helping hand. By his friends you shall judge him.

The Production of Silver

Herewith we give the statistics of the world's production of silver, in ounces. It will be noted that the total output, which declined in 1916 as compared with 1915, has increased slightly during the last two years. The maximum output was 226,000,000 ounces in 1911. Whereas the quantity produced in late years has varied but little, it will be seen that the value of the output has nearly doubled. The figures for last year are approximate. We note that the reports of the U. S. Mint confuse Burma with British India and that Australia is not credited with the silver in the lead and zinc concentrates exported, so that we have found it necessary to make sundry corrections. Broken Hill alone contributed 8,300,000 ounces in 1915, against the normal annual yield of 13,300,000, as in 1914. The increased output from Burma is due to the profitable activities of the Bawdwin mine of the Burma Corporation. Mexico shows a recovery, which will be accentuated this year by reason of recent favorable developments at Pachuca; likewise the mines of Nevada are likely to do better on account of the discoveries at Divide. The silver from India, Rhodesia, and the Transvaal is a by-product of gold mining. It is hardly to be expected that there will be a marked increase in the quantity of silver produced this year because the stimulus to the exploitation of the mines producing silver alone will not compensate for the decrease in the yield of silver as a by-product from the base-metal mines, notably those in which copper is the principal metal.

	1915	1916	1917	1918

Recovery of Copper From Flotation by Leaching

By PERCY R. MIDDLETON

The use of the flotation process for the treatment of low-grade copper ores has introduced an additional problem in the form of smelting the finely divided concentrate resulting from the operation. The majority of Australian mining companies that adopted the flotation process were equipped with blast-furnaces and consequently some method of sintering had to be adopted before the concentrate could be successfully smelted. Under Australian conditions the cost of sintering is high, and considerable trouble has been experienced in obtaining a satisfactory product. The smelting and railroad facilities of the United States seem to have caused the American mining companies to overlook the fact that an increased profit could be made by treating the concentrate on the ground in preference to shipping it to the smelter.

It is well known that the sulphides of copper can be converted into the sulphate by roasting, and if the right conditions are maintained, from 85 to 90% of the copper may be turned into a water-soluble salt. Utley Wedge gives particulars of experiments on the sulphatizing roasting of copper ores and concentrates, in the Transactions of the A. I. M. E., Vol. XLIV (1912), and in view of his results it is hard to understand why more attention has not been given to this subject. Mr. Wedge conducted his experiments in a muffle-furnace, but I have found no difficulty in obtaining satisfactory results in the ordinary type of roasting-furnace. To obtain a satisfactory sulphatizing roast, skill and a thorough knowledge of furnace conditions are required; the cause of failure hitherto has been lack of the essential skill and knowledge of how the roast should be conducted. As in the majority of metallurgical operations, no fixed method can be applied to all ores. A wide variation in range of temperature will be found necessary to obtain the best results. I have made a special study of this subject and have roasted over one thousand tons of various ores and concentrates.

The recovery of the precious metals from the leached residues may appear at first to present insurmountable difficulties, but on investigation these disappear. Things that were impossible ten years ago, owing to the lack of apparatus, are now practicable. The improvement in mechanical appliances, for example, the vacuum-filter and the Dorr decantation system, has made commercially possible many processes that were formerly regarded as metallurgical curiosities. The extraction of copper after roasting and leaching is usually so complete that the cyanide process may be applied for the recovery of the gold and silver, without excessive consumption of cyanide, or the gold may be recovered by chlorination and the silver by either sodium hyposulphite or brine. Laboratory experiments have shown satisfactory results with cyanide; however, it is an open question whether the advantage of using one solution for the recovery of both gold and silver would off-set the danger of incomplete washing in a large plant. A good extraction of gold has been effected with chlorination in large-scale tests, but the ore on which the experiments were conducted carried practically no silver; on the other hand, laboratory experiments show that after chlorination the silver is in a condition suitable for extraction by either sodium hyposulphite or brine.

At the conclusion of some experimental work on the leaching of low-grade sulphide ores for the Mt. Lyell M. & R. Company, in Tasmania, I suggested the roasting and leaching of the flotation concentrate and was instructed by this company to carry out a complete investigation. Similar work was conducted for other Australian mining companies and in each case satisfactory results were obtained.

The following is a summary of some of the results of the above investigations:

CONCENTRATE No. 1. Assay: Cu 9.11%, Fe 26.7%, S 29%.

This sample was roasted at a temperature not exceeding 600°C., the product being leached with 5% sulphuric acid solution, with the following result:

Weight of sample before roasting, 1000 gm.; copper, 9.11%. Roasted product leached with two litres of 5% sulphuric acid solution. Resulting solution contained 45 gm. copper per litre.

Copper extracted, 90 gm., or 98.7%.

CONCENTRATE No. 2. Assay: Cu 20.52%, Fe 28.2%, Au 1.81 oz.

Roasted at a temperature not exceeding 650°C.

Weight of sample before roasting, 1000 gm.; copper, 20.5%. Roasted product leached with two litres of 5% sulphuric acid solution. Resulting solution contained 100.44 gm. copper per litre.

Copper extracted, 200.88 gm., or 97.9%.

CONCENTRATE No. 3. Assay: Cu 5.8%, Fe 35.0%, and Au 0.587 oz.

Roasted at a temperature not exceeding 650°C.

Weight of sample before roasting, 1000 gm.; copper, 5.8%. Roasted product leached with two litres of 5% sulphuric acid solution. Resulting solution contained 28.0 gm. copper per litre.

Copper extracted, 56 gm., or 96.5%.

Cyanide tests for the recovery of gold were conducted on the residue from the No. 2 and 3 leaching experiments. The residues were given a lime wash and then treated with cyanide solution. The copper present did not interfere with the gold extraction, no trace of troublesome cyanicides being detected. The average gold extraction over a number of tests was 90% and the consumption of cyanide about 1.5 lb. per ton of residue treated. Chlorination also gave satisfactory results when the acid-soluble iron in the roasted product was below 1%. In order to confirm the copper extraction obtained in these laboratory experiments, a bulk-test was conducted under actual working conditions in the Edwards metallurgical works, at Ballarat, Victoria. The roasting was performed in a 7-panel duplex Edwards furnace and the product was leached by percolation in vats fitted with filter-bottoms. Scrap-iron was used to precipitate the copper. The furnace was operated continuously at a temperature of about 650°C. The roasted material was dampened with water before being charged by hand into the leaching-vats, about 20 tons forming the charge, which was covered with a 5% solution of sulphuric acid; after 24 hours contact, this solution was drawn from the bottom of the vat into a launder connecting with the precipitation vats. The charge was then washed free from copper with water, which also went to the precipitation vats. In the above manner 110 tons of concentrate was roasted and leached with the following results: The tonnage treated was 110 tons of concentrate containing 7.6% copper, and the copper produced amounted to 19,856 lb. cement copper assaying 80% Cu, showing an extraction of 95%.

This bulk-test was conducted with the object of determining whether the concentrate could be roasted with satisfactory results on a working scale and did not include any experimental work on precipitation. The fact that copper can be commercially recovered from sulphate solutions by electrolysis has been established beyond dispute at Chuquicamata, in Chile, and at Ajo, in Arizona. The electrolytic deposition of copper from solutions resulting from the leaching of roasted ore is the ideal method of precipitation, as sufficient acid can be regenerated to carry on the process, thus obviating the need for an expensive acid plant, and the amount of acid-soluble iron in the roasted product is under control, being regulated by the furnace conditions; therefore the amount of 'bleeding' would not be as great as in the case of electrolyzing solutions resulting from the leaching of oxidized ores where there is no control over the amount of iron entering the electrolyte at each cycle.

In order to illustrate the possibilities of this process the following working-costs were compiled from figures obtained in working-scale tests: Assuming the concentrate to contain 12% copper, 9 oz. silver, and 0.25 oz. gold, and treating 100 tons per day, the items of cost would be:

Roasting	$0.30	
Leaching	0.15	
Gold and silver leach	0.75	
Handling residues	0.10	$1.30
Electrolytic deposition:		
Power, 240 kw hr @ 1c	$2.40	
Labor, etc.	0.70	3.10
Losses:		
5% of copper, 12 lb @ 15c	$1.80	
Silver, 1 oz. @ $1.01	1.01	
Gold	0.50	3.31
Capital account (retirement of $300,000 in five years):		
100 tons × 360 × 5 = 180,000 tons = $\frac{300}{180}$		1.66
Net cost		$9.37

The smelter returns from such a concentrate would be approximately as follows:

12% copper = 240 lb. less 15 lb. = 225 lb. @ 15c. less 3c.	$27.00
9 oz. silver @ 95% of $1.01 = 96c. × 9c.	8.64
0.25 oz. gold @ $19	4.75
Value of metals less smelter deductions	$40.39
Freight and treatment	12.00
Net daily returns per ton of concentrate	$28.39

Ratio of concentration, say, 3:1

$\frac{\$2839}{100 \times 3}$ = $9.46 net return per ton of crude ore

Summary of Costs of Both Processes

Smelting:		
100 tons @ 240 lb. copper per ton, 24,000 lb. at 15c.		$3,600
100 tons @ 9 oz. silver per ton, 900 oz. silver @ $1.01		909
100 tons @ 0.25 oz. gold per ton, 25 oz. gold @ $19		475
Total value of all metals		$4,984
Returns from smelter = 100 × 28.39		2,839
Cost and losses by smelting		$2,145
Costs and losses per ton of concentrate	$21.45	
Costs and losses per ton of crude ore	7.15	
Net returns per ton of crude ore	9.46	
Roasting and leaching:		
Total value of metals as above		$4,984
Costs and losses, 100 tons @ $9.37		937
Net returns by leaching		$4,047
Costs and losses per ton of concentrate	$9.37	
Costs and losses per ton of crude ore	3.12	
Net returns per ton of crude ore	13.49	

Difference in favor of roasting and leaching, $4.03 per ton of crude ore.

If the working-costs and losses for roasting and leaching are raised to $12 per ton, instead of $9.37, the net return per ton of crude ore is changed to $12.61 per ton, the difference in favor of leaching being $3.25 per ton of crude ore.

A plant to treat 100 tons of concentrate per day would consist of two 13-panel duplex Edwards furnaces, five Dorr counter-current thickeners for copper leaching, four Dorr counter-current thickeners for gold extraction. If chlorination were employed a vacuum-filter and another series of Dorr thickeners would be required for silver extraction. In each case the thickeners would be 15 ft. diam. based on a settling-area of four square feet per ton of roasted product. In addition to the above plant, electrical equipment would be required for the precipitation of the copper.

Palau is a trade name for an alloy containing about 80% gold and 20% platinum. The metal is somewhat darker in color than platinum, but resembles it otherwise. Its melting-point is 1370°; this is higher than that for gold, but 400° lower than that of platinum. The U. S. Bureau of Standards found that a crucible of this alloy was comparatively free from iron, and that its loss on heating to 1200° was less than that of a platinum crucible containing 2.4% of iridium. The resistance to acids and salts is comparable with that of platinum. The ware is suitable for fusions with sodium carbonate, but is decidedly attacked by fused pyro-sulphates. Crucibles of palau could not be used for work at high temperatures on account of its relatively low melting-point.

Use of Army Gas-Masks in Atmospheres Containing Sulphur Di-oxide

By A. C. FIELDNER and S. H. KATZ

*INTRODUCTION. The use of toxic gases in warfare has led to the development of an entirely new type of respiratory appliance, namely, the gas-mask, which promises to fill a long-felt want in the chemical and metallurgical industries. Heretofore workmen around plants using processes in which acid fumes are given off made shift to protect themselves, in a more or less inadequate manner, by wearing moistened handkerchiefs, or respirators containing wet sponges, over the mouth and nose. The close of the War now makes available the army type of gas-mask, which is admirably adapted to filtering out many chemical fumes and acid vapors from inspired air, provided the concentration of gas is low, less than 1 or 2%.

The possibility of using army masks around smelters and sulphide roasters for protecting the workmen from sulphur di-oxide fumes was suggested, almost a year ago, by George S. Rice, Chief Mining Engineer of the Bureau of Mines, and at his request several patterns of army masks were tested in various concentrations of sulphur di-oxide to determine the degree of protection afforded. Owing to the pressure of military work and the inability of obtaining masks for industrial use, this investigation was not completed until after the signing of the Armistice. The work is now completed, and the results are given in this publication.

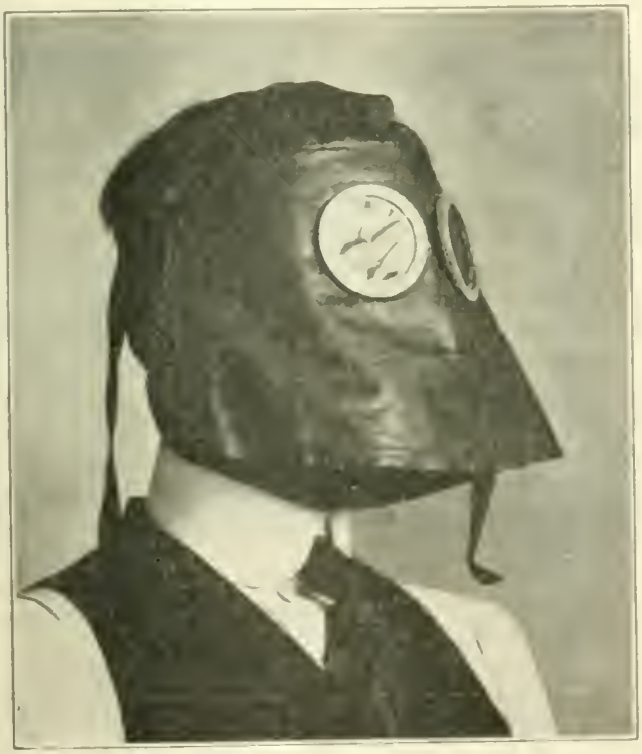

FIG. 1. EARLY FRENCH TYPE OF MASK

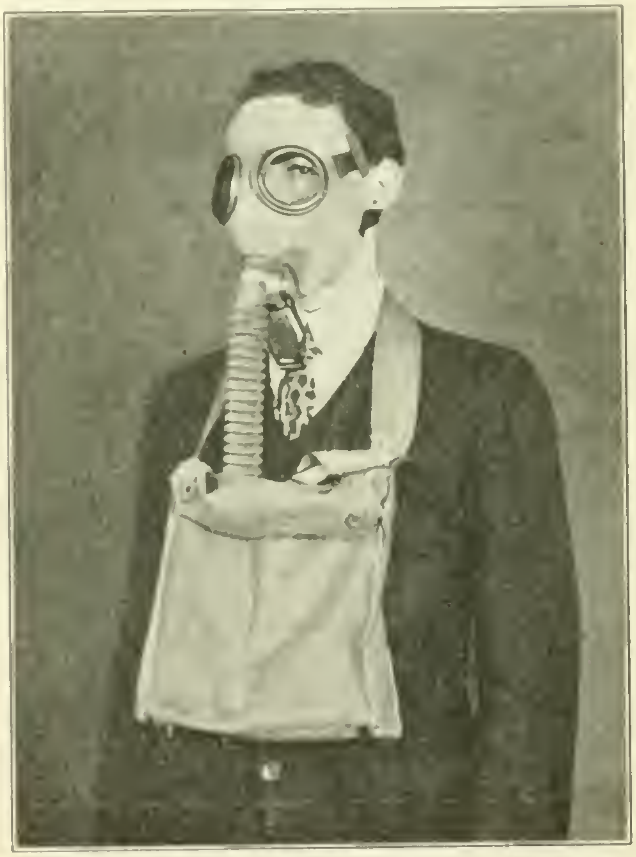

FIG. 2. THE TISSOT GAS-MASK

PHYSIOLOGICAL EFFECT OF THE GAS. Sulphur di-oxide is an irritating irrespirable gas, relatively non-toxic as compared with carbon monoxide or oxides of nitrogen. There is but little danger from sulphur di-oxide poisoning, as the fume is so irritating that the victim is compelled to seek air at once. In extreme cases[1] of high concentrations, when the victim cannot retire from the fume, death may result from respiratory spasms and asphyxia. Ordinarily, however, workmen exposed for some time to a mild degree of sulphur di-oxide poisoning complain of headache, anorexia, spasmodic cough, sneez-

ing, hemoptysis, bronchitis, constriction of chest, gastro-intestinal disorders, conjunctivitis, smarting of eyes, lachrymation, and anemia. For these symptoms workmen soon acquire toleration. The inhalation of large quantities of sulphur di-oxide produces ulceration of the mucous membrane.

The Selby Smelter Commission[2] made a thorough investigation of the effect of various concentrations of sulphur di-oxide on the senses of a number of persons. The average results of these tests are tabulated below:

3 to 5 parts per million, by volume—Plainly or faintly detectable by smell or taste.

8 to 12 parts per million, by volume—Slight throat irritation and tendency to cough

20 parts per million—Distinct throat irritation, coughing, constriction of chest, lachrymation, and smarting of eyes

50 parts per million—More pronounced irritation of eyes, throat, and chest, but possible to breathe several minutes.

150 parts per million—Extremely disagreeable but could be endured for several minutes.

500 parts per million—So acutely pungent as to cause a sensation of suffocation, even with the first breath.

With no concentrations of less than 50 parts per million was there produced any feeling of nausea, and the tendency to nausea with the highest concentrations was only slight.

We repeated some of these experiments with substantially the same results: 370 parts per million (0.037%) could be endured for half a minute.

TESTS OF ARMY GAS-MASKS. The early French type of mask, shown in Fig. 1, consists of 40 thicknesses of cheese-cloth, fashioned to fit over the entire face, from neck over chin to the hair above the eyes from ear to ear. Suitable rubber-web bands held the mask closely to the face. Cellophane eye-pieces were built into the mask at the eyes. The 10 outside layers of cheese-cloth were impregnated with an unsaturated oil; the next 10 layers held an alkaline material; the next 10, hexamethylene tetramine; and the 10 next the face, nickel sulphate. The tests were made in a large air-tight gas-chamber, in which the sulphur di-oxide atmosphere was produced by burning sulphur. The air was well stirred by two electric fans, running continuously throughout the tests. The concentration of sulphur was determined by titration with iodine. After the required concentration was reached, two observers, wearing carefully adjusted masks, entered the room. The results are given in Table I.

Table I

Effects produced by atmospheres containing various proportions of sulphur di oxide on persons wearing French patterned masks.

Test No	Time	SO$_2$ by iodine, %	Effect on wearer of apparatus in atmosphere
1	2:15 2:31:00 to 2:30:45	0.57	Sulphur di oxide penetrated masks. The eyes could feel it but were not disturbed much. The biting was severe in the air passages of the nose and throat. It could also be felt in the bronchial tubes and lungs. Observers could remain in this atmosphere only 15 seconds.
2	2:46 2:58:00 to 3:03:00	0.43	The observers could just bear the sulphur di-oxide that came through the masks. The biting in the air passages extended all the way to the lungs. Coughing was caused. The eyes were not bothered. The breathing was deep and difficult. In case of necessity one could probably travel ½ mile in this condition. It was thought best not to remain in this atmosphere longer than 5 minutes. After coming into the fresh air, all the sulphur di-oxide disappeared from the mask after three inhalations.
3.	3:24:00 to 3:27:00	0.24	At first one of the masks leaked at the sides, so that the eyes were bothered. After fixing this, the atmosphere was much better. The biting in the air-passages was not so severe, but coughing was caused. It is probable that one could stand this atmosphere one hour, in case of necessity.
4.	4:00	0.16	No difficulty was experienced in this atmosphere. The sulphur di-oxide was noticeable and the throat was slightly irritated, but work could be done with hardly more trouble than that due to the mask itself.

From the experiments in Table I, it may be concluded that an atmosphere containing 0.16% of sulphur di-oxide may be safely entered and work performed by a person wearing a mask such as used in the experiments. Even though a mask were worn, it would be dangerous to attempt work in an atmosphere containing 0.2% of the gas, unless means of immediate exit were at hand and an observer watching from a place of safety to effect a rescue in case of necessity.

Prolonged exposure to the gas, even in moderate concentrations, is undoubtedly injurious. Five hours after the close of the above experiments, the observer who had been most exposed felt a soreness through the lungs and throat and the voice was slightly husky. The discharge from the nose was increased, and was slightly pink from blood. The next day he felt normal.

The French type mask is an unpleasant apparatus to wear at best, although it imposes no marked hardship on the wearer. The face is heated, and the atmosphere breathed necessarily contains much exhaled air, and is hot and close. To determine the composition of the atmosphere within a mask while worn by a person at rest, two samples of gas were taken from a point ½ inch above the nostrils—the first, during periods of exhalation, the second, during periods of inhalation. The results are given in Table II.

Table II

Composition of atmosphere within mask while worn in pure air.

No.	CO$_2$	O$_2$	N$_2$	
1.	2.90	17.41	79.69	Sample taken during exhalation
2.	1.37	19.15	79.48	Sample taken during inhalation

These tests show the bad effect of the large 'dead space' in this type of mask. Even while at rest the wearer has to inhale 1.37% of carbon di-oxide, which contributes to the oppressive feeling produced by this mask. Aside from the question of re-breathing a certain proportion of exhaled air, this type of mask furnished so little protection against sulphur di-oxide that it is of no practical value for use in the industries.

The standard U. S. Army gas-mask of the mouth-piece type is shown in Fig. 2 and 3. It consists essentially of a face-piece of rubberized fabric, impermeable to gas, connected to a canister containing the absorbents by a short length of flexible rubberized tubing. The wearer breathes through a rubber mouth-piece, the nose being closed by a spring-clip, mounted on the inside of the mask. Leakage through the face-piece will only affect the eyes of the wearer, as the gas cannot enter the lungs. The inhaled air enters the bottom of the canister through a disc-valve

---

Holmes, J. A., Franklin, E. C., and Gould, R. A., 'Report of the Selby Smelter Commission', Bureau of Mines Bull. 98, pp. 172-175 that closes on exhalation, the expired air passes out through a rubber flutter-valve, projecting downward from the metal elbow-tube just outside the face-piece.

The type F standard army canisters shown in section in Fig. 1 is 5½ in. high and contains 42 cu. in. of a mixture of cocoanut charcoal and 'purple' soda-lime and two cotton-wadding filter-pads, placed at one-third and two-thirds distance from the bottom, respectively. One of us, wearing this outfit, entered the gas-chamber containing a concentration of 0.46% sulphur and remained one hour, without detecting any gas whatever, except on one occasion, when the mask was disarranged, and then sulphur di-oxide penetrated to and irritated the eyes. On adjusting the mask and clearing the face-piece, the gas disappeared, and no discomfort whatever was experienced thereafter from that source. During a part of the time, work was done on a bicycle dynamotor.

More sulphur was then burned, until a fog was produced in which objects could not be distinguished at distances beyond four feet. Analyses showed that the concentration was 1.17% sulphur di-oxide. No discomfort of any kind could be felt by the wearer, other than that due to the mask itself.

Life of Canisters in High Concentrations. Tests were made to determine the life of the standard type F Army canister in an atmosphere containing 5% sulphur di-oxide. The gas was put up in the chamber from a cylinder of liquid sulphur di-oxide, attached to the chamber. Analyses of the chamber-gas were made by drawing two litres of gas through a standard iodine solution and titrating back with standard sodium thiosulphate solution. Twenty canisters were tested, in lots of 10 each. The men did not enter the chamber, but were seated outside, wearing the face-pieces, which were connected to iron pipes that passed through the walls of the chamber. The canisters were attached to the other end of these pipes inside the chamber. As soon as a man detected gas coming through his canister, as shown by throat irritation, the time was taken, and the canister was considered exhausted.

Tested under these conditions, the 20 canisters served to remove all the gas for periods of time varying from 18 to 41 minutes. The average service time was 29 minutes. The large variation in service time for the individual canisters was due, in part, to differences in the canister fillings, but mostly to differences in the breathing rates of the men. Individuals breathe different amounts of air. A small man may breathe only 5 litres per minute when at rest, while a large individual may require 10 or 12 litres. The average rate of a number of men, when at rest, is about 8 litres per minute. Moderate exercise increases the rate to approximately 30 litres, and vigorous exercise causes a breathing rate of 60 to 70 litres. Hence, the efficient life of a gas-mask canister is proportionately less when the wearer is engaged on continuous work.

In making these tests with high percentages (5.07%) of sulphur di-oxide, the canisters became quite warm after 15 minutes use. A temperature of 80°C. was noted

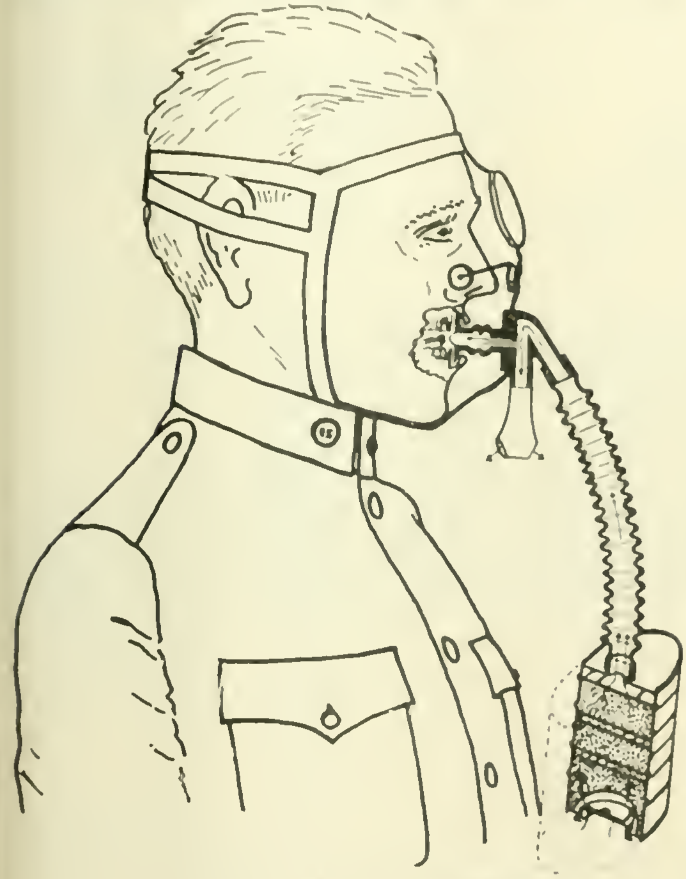

FIG. 3. U. S. ARMY GAS-MASK

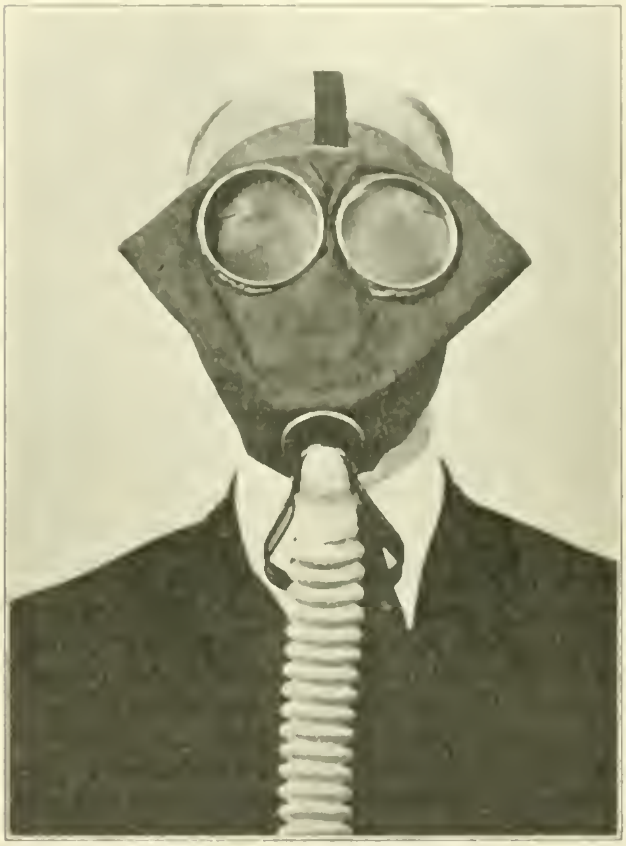

FIG. 4. U. S. ARMY GAS-MASK WITH MOUTH-PIECE

in some of the canisters. This elevated temperature made breathing rather uncomfortable toward the end of the test; however, all the men were able to continue breathing through the canisters until the gas finally penetrated the absorbent.

Practical Tests. Several Army masks of the mouth-piece type (Fig. 1 and 2) fitted with standard type F canisters, containing soda-lime and charcoal mixture with two cotton-wadding filter-pads, were tested under practical conditions by James Kane Murphy, Assistant Superintendent of the Washoe reduction works of the Anaconda Copper Mining Co., at Anaconda, Montana. The following paragraphs are quoted from his report:

"On October 23, 24, and 25, we had considerable repair work to do on one of our Cottrell treaters; this treater takes one-quarter of the gas from roaster No. 2. During the repair-work on this treater, it was shut off as tight as possible, but there was such a leakage of SO_2 gas that it was impossible for a man to enter the treater to do any work. The iron-workers repairing this treater were able, two at a time, to put on these masks, and do their repair-work in the treater. The men stayed in about 20 minutes at one time; by that time, the heat and dust caused them to come out, but the masks were very satisfactory and work could be done with them by proceeding slowly. One test on these masks was performed in the No. 2 roaster ventilating-tunnels when flotation calcine was drawn into cars ahead of the man with the gas mask on. It is absolutely impossible for a man without a mask to even attempt to stay in this place. Most of the dust coming from the cars, which were being loaded ahead of the man with the gas-mask, will pass through 200-mesh, but none of the men wearing a mask in this place had any trouble with dust. A third mask was tested in a very high concentration of gas. The mask was carefully adjusted about the face and the person making the test was in an atmosphere containing about 5% SO_2. E. A. Bernard, Superintendent of Calcining, personally put the mask on in this atmosphere, besides two other men. All decided that the gas came through the canister. This test was made on gas from the top hearth of an Anaconda type of roaster-furnace. The hearths on this furnace are similar to a Wedge roasting-furnace. A steady wind was blowing against the east side of the furnace, so all doors on the top floor were opened, thus forcing a good part of the furnace gases out of the west doors. The testers stood as close as possible to the doors through which the gas came. This gas contains some SO_3, considerable moisture, dust, and some AS_2O_3, besides the SO_2. If possible, we would like to have two more canisters for further testing of these masks, as they have proved to be very valuable in certain places, from the industrial point of view."

This reports that the simple Army gas-mask is exceedingly valuable around sulphide roasters and, in fact, any industry in which sulphur di-oxide is given off. The third test in which gas penetrated the canister illustrates the limitation of this type of protective appliance. It must not be used in too high a concentration of gas. In this case, the percentage of SO_2 was probably higher than 5% as tests at the American University Experiment Station of the Chemical Warfare Service have shown that the standard Army canister will remove 5% of sulphur di-oxide for at least 15 minutes.

Special Canister Filling. The standard Army canister contains 40% soda-lime and 60% charcoal. The charcoal is of less value in absorbing sulphur di-oxide than soda-lime. Hence, for use in sulphur di-oxide and dust an all soda-lime canister with cotton-wadding filter-pads will last from 50 to 100% longer than the standard canisters used in the Anaconda tests. This is shown in the comparative canister tests with different fillings against ½% SO_2.

Table III

Service times of canisters with standard and special fillings.
SO_2 concentration, 0.5% or 13.0 Mg per litre; relative humidity, 50%; average temperature, 26°C.

*Standard, 60% charcoal, 40% soda-lime...	32	36
Special, 100% charcoal....................	7	57
Special, 100% soda-lime	54	..

*Average of five canisters tested.

The life or service time of the canister is the time in minutes during which all traces of SO_2 are absorbed by the canister. The break-down of the canister is shown by the change in color of a sensitive potassium iodide-starch solution through which the effluent air from the canister is bubbling during the test.

Advantages of Larger Canister. The standard Army canister described in the foregoing tests contains 42 cu. in. of absorbent, weighs 1⅝ pounds and has a resistance to flow of 3½ to 4 in. water-column at 85 litres per minute flow. This high resistance obliges men to work rather slowly while wearing the mask. A second disadvantage to which Mr. Murphy has called special attention is the short service time of the absorbent.

Both of these defects can easily be remedied by increasing the cross-sectional area of the canister without increasing the height in proportion.

Type Recommended. Although the mouth-piece type of mask was found fairly satisfactory in practical use, it is believed that the later type of Tissot mask (Fig. 4) in combination with a 100 cu. in. soda-lime canister will prove the best outfit for exclusive use in sulphur di-oxide and acid gases. The elimination of mouth-piece and nose-clip increases the comfort, and enables the wearer to keep it on for hours at a time. The large eye-pieces held rigidly in proper position by the well-fitting substantial face-piece, afford a large angle of vision, thereby greatly increasing the efficiency of the workman wearing the mask. He should be able to do substantially the same amount of work as without the mask in a normal atmosphere.

Other Uses of Respirators. Aside from the many metallurgical operations in which sulphur di-oxide is given off, a respirator or mask designed for this purpose should be useful in sulphite-pulp and paper mills; in sulphuric acid plants and in fact for protection against any acid gas such as chlorine, phosgene, carbon di-oxide, hydrocyanic acid, oxides of nitrogen, and hydrochloric acid.

LIMITATIONS OF GAS MASKS. In closing this paper, we feel it necessary to issue a most emphatic warning against the indiscriminate use of gas-masks for any and all purposes. The soldiers in the Army have been taught that their mask will protect them absolutely against any gas the enemy may put up. These men, on returning to civil pursuits, carry this idea with them. They will not realize that the extremely poisonous gases used in warfare are chemically active, and, therefore, combine readily with the absorbents of the mask. Furthermore, outdoor gas concentrations seldom exceed a few hundredths of one per cent. Some of the gases that are successfully absorbed by the mask at these battlefield concentrations will immediately penetrate it when present in quantities of 1 or 2%. In fact, the Army mask is useless against many of the most common industrial gases, as for example, carbon monoxide, ammonia, natural gas, producer and blast-furnace gas, mine-gases, coal and water gas, and probably any gas when occurring in concentrations exceeding 5%. In such cases the self-contained oxygen-breathing apparatus must be used, as the mask does not supply any oxygen whatever. In view of these serious limitations, the gas-mask should be used only with the advice of an expert who has a thorough understanding of the limitations of this apparatus.

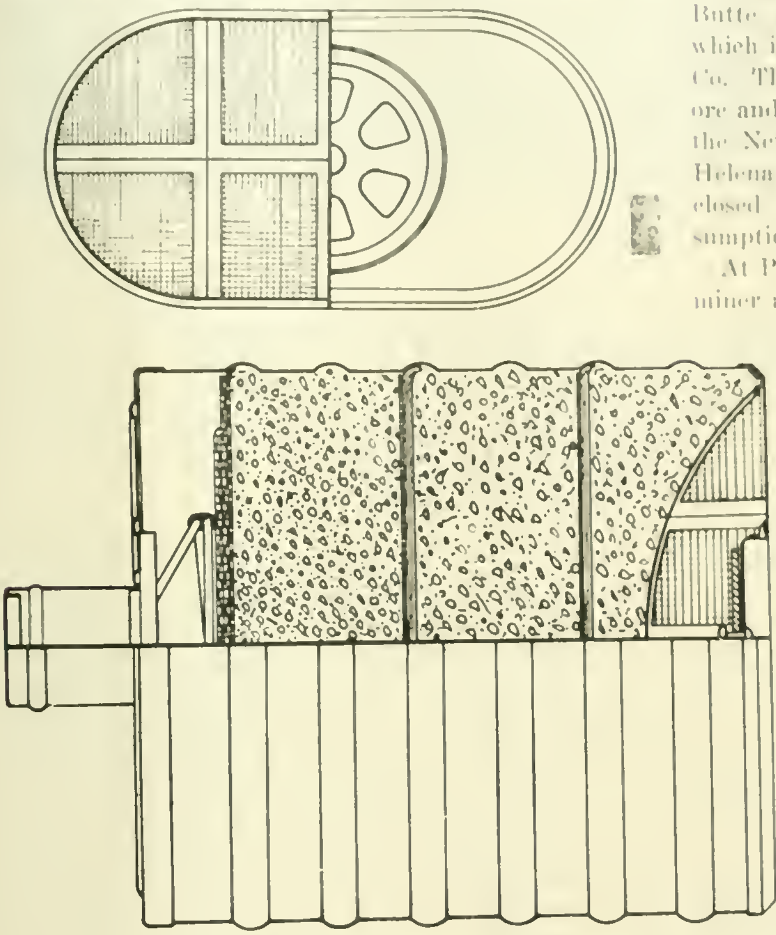

FIG. 5. AMERICAN CANISTER TYPE OF MASK

Much of the charcoal used in Army masks was made by the Pacific Gas & Electric Co. at San Francisco.

Manganese

There is little change in the position of manganese ore from that of March. Reports from the various districts show that production of ore still continues, but operations are confined to high-grade deposits, particularly in Arkansas, Arizona, Montana, and Virginia. It is very probable that mining will be resumed in Georgia and New Mexico, where chemical ores are known to occur in considerable quantities.

In Montana, the only producer of manganese ore at Butte is the Clark-Montana Realty Co. [Elm Orlu] which is operating on a contract with a Pittsburgh Steel Co. The contract calls for 1000 tons per month of crude ore and concentrates. The ore is treated at the plant of the New York-Montana Testing & Engineering Co. at Helena. The Ophir mill of the Butte-Detroit company closed in December, but is being kept in order for resumption of operations should occasion permit.

At Philipsburg the Philipsburg Mining Co. is the only miner and shipper; however, other operations were carried on until April 5. The Philipsburg Mining Co. is extracting 160 to 200 tons of ore per day, which assays 32.9% Mn and 37.7% SiO_2. This ore is treated in the company's mill, which has a daily capacity of 75 to 100 tons of concentrates, averaging 50.3% Mn and 10.4% SiO_2. No crude ore is shipped, but the concentrates are taken by Eastern concerns dealing in chemical ores. The concentrates are reported to contain 73.5% MnO_2.

Aside from the above-mentioned work and the small-scale operations in the Batesville district, Arkansas, manganese mining is practically at a standstill.

The market price of manganese ore has changed little during the past month, especially for the higher grades. Both domestic and foreign ores are quoted at 55 to 65 cents a unit f.o.b. South Chicago, and c.i.f. Atlantic ports. The domestic ore is, however, purchased on a long ton unit basis, while the foreign ore is on a short ton basis. Chemical ore is selling at $85 to $100 per gross ton, delivered, 80% basis. Powdered chemical ore is quoted at 7 to 8 cents per pound for 80% grade.

Imports during March totaled 48,238 tons, over double those in February. Brazil and Cuba contributed 44,000 tons.—W. R. Crane in April report of U. S. Bureau of Mines.

DURING the War, the lead smelter of the Broken Hill Associated Smelters, Proprietary, Ltd., at Port Pirie, South Australia, was enlarged and its capacity is now 165,000 short tons annually, making it the largest plant of its kind in the world. Most of the lead concentrates produced by the Broken Hill mines of New South Wales are reduced in this plant. Many improvements are in progress. Large quantities of refined silver are shipped.

Pyrite, Sulphur, and Sulphuric Acid

By R. R. HORNOR and A. E. WELLS

General. The pyrite and sulphur situation during April was about the same as in March, with probably somewhat greater demand for these materials. Producers are carefully watching developments in the sulphuric-acid industries and in other branches using these materials, and are prepared to bid for any business that may be offered. The outlook in the acid business is encouraging, and it is predicted that a few months will see the industry back to a normal basis. The same may be said of the industries using sulphur exclusively. Stocks of pyrite and sulphur in the hands of consumers are being diminished gradually, and it is expected that they will be in the market for new material in a short time. However, they prefer to hold off as long as possible before placing contracts, anticipating that much more favorable prices can be obtained than are now being quoted. Ore is quoted at 18 to 20 cents per unit.

Pyrite. In New York State, the St. Lawrence Pyrites Co. is now approaching a normal monthly output of 4000 tons of 42% concentrate. The New York Pyrites Co. is shipping over 1400 tons of 27 to 30% ore.

In the Mineral district of Virginia the Sulphur mine produced 3500 tons of lump ore and concentrate in April, and the Armenius mine from 1000 to 1200 tons. In the Dumfries district the Cabin Branch yielded 2500 to 3000 tons, one-third lump ore, the remainder concentrates.

The Spanish pyrite situation is greatly improving, and there is a growing demand in both the northern and the southern markets of the United States.

Sulphur. The large sulphur companies of Louisiana and Texas continue to add to their reserve stocks of sulphur, and it is estimated they now have more than 1,250,000 tons above ground. The Texas Gulf Sulphur Co., since starting operation about the middle of March, has placed in production additional wells, and the present output is reported as 1000 to 1500 tons of sulphur per day.

It is rumored that the sulphur companies are preparing to invade the sulphuric-acid field in competition with pyrite, and that they have already made substantial reduction in price in the northern markets. A price of $22 per ton, f.o.b. New York and Boston, is said to have been made.

Sulphuric Acid. As a result of an inquiry made of the acid manufacturers at the meeting in New York on April 2, it was evident that the rate of production of acid in the East during the first four months of 1919 was only about 330,000 tons per month, or about 60% of the rated capacity of all commercial plants in the East. However, distribution of this production is not the same in the South as in the North. In the South, that is, south of Virginia and Kentucky, most of the fertilizer plants are running at or near capacity, and the average rate of production of the plants is probably 90% of the rated capacity. In the North, however, production is only 50%. We have, therefore, a rate of production in the South of 120,000 tons per month, and an average in the North of 210,000 tons. These figures apply only to those plants east of the Mississippi. The output west of the Mississippi is estimated to be 30,000 tons. Adding these estimates of present production, we have a total for the United States of 360,000 tons per month, or 4,320,000 tons (basis of 50°B.) per year, which is approximately 320,000 tons more than the production of 1914, and this will undoubtedly increase as general business conditions throughout the country improve. Data compiled during the third quarter of 1918 showed that the general commercial business in the North during that period required 260,000 tons of acid. This is nearly 25% more than the rate during the first quarter of 1919. If stocks remained the same, this would indicate that the general commercial business had been reduced by 25%. However, as stocks have been increasing, and acid production at the same time has been decreasing, and is probably even less than 50% of the capacity of the plants at this time, the indications are that the general chemical business has been curtailed by more than 25%. The amount of acid owned or controlled by the Government, about 100,000 tons, is, therefore, somewhat greater than one-half of a month's supply for the demand in the North under present business conditions.

Blast-furnaces can economically use ores with an average content not much below 40% Mn and not much above 12% SiO_2. However, there are large quantities in the United States, particularly in the West, that contain a smaller proportion of manganese and a greater proportion of silica. There is a possibility of utilizing such ores by electric smelting. An electric-furnace can be constructed more rapidly than a blast-furnace. It can be operated economically in smaller units than a blast-furnace, and therefore can be placed wherever a suitable supply of ore and a suitable water-development are found near each other. An ore deposit inadequate to supply a modern blast-furnace would last a rather large electric-furnace for a considerable time. Hence the smaller electric unit can be so placed as to require smaller transportation charges than would be necessary for a more distant blast-furnace. The product that could be economically made at such an electric-furnace plant would be not ferro but silico, as this permits a much higher recovery of manganese. Silico is not used to any considerable extent in the United States, but it is in Europe. There is, however, a large quantity of steel made in this country in whose manufacture both ferro-manganese and ferro-silicon is used, and silico-manganese could just as well be used in this case. The utilization of ores low in manganese and high in silica is therefore dependent upon the education of the steel industry to use silico-manganese where a combination of ferro-manganese and ferro-silicon is now employed.—H. W. Gillett and C. E. Williams in U. S. Bureau of Mines bulletin 'Electric Smelting of Domestic Manganese Ores'.

MINING FOR NICKEL IN NEW CALEDONIA

Willet G. Miller, Canadian Geologist

AN INTERVIEW, By T. A. RICKARD

Dr. Miller, you are a Canadian?

Yes, I was born in Norfolk county, Ontario.

Was your father interested in mining?

No, he hadn't any technical training, but he was interested in natural history—trees, flowers, and rocks—and he brought home the first collection of fossils that I had ever seen, from Manitoulin island in Lake Huron.

So you acquired some taste for geology?

I didn't pay much attention to mineralogy and geology until I went to the University. I had never seen compact rock in place anywhere in my native county.

What was your schooling?

I went to country schools, and then to the Port Rowan high-school, and stayed there until I had completed the first year's work in the University of Toronto. Before completing my course I stayed out one year, and had the experience of teaching in the high-school. That was owing to the fact that our local high-school was short of a teacher and my old master wanted me to put in some time with him; and I am glad I did, because it gave me an opportunity of planning the course and appreciating more what it meant.

In what year did you graduate at Toronto?

In 1890.

At the time of graduation, had you any plans for a career?

No; during my university course I specialized in chemistry and took mineralogy and geology as well. After graduation I was appointed fellow in mineralogy and geology and held the fellowship for three years, until 1893. The fellowship was intended to give one an opportunity to do post-graduate work, but it required the holder of it to do some teaching—take part in the instruction. During the summers while I was a fellow I was a field-assistant on the Geological Survey of Canada, under Dr. Robert Bell, in the area along the north shore of Georgian Bay and Lake Huron, sometimes known as the classic Huronian area.

So you drifted into mining?

No; I chose mineralogy and geology as my subjects at college. It was fortunate for me that I was appointed a fellow. In 1893, at the termination of my fellowship, I was appointed lecturer in geology in the newly founded mining school of Queen's University, at Kingston, Ontario. Later I became a professor. Altogether I spent nine years at Queen's. During the time I was there I took short courses of post-graduate work at the universities of Chicago, Harvard, and Heidelberg, more with the object of becoming acquainted with the men and methods than of any particular study.

That brings us to 1902.

In 1902 I was appointed Provincial Geologist of Ontario. The term 'Provincial' is not always understood; it means 'State'. During part of the nine years I was at Queen's I had been doing special work for the Ontario Bureau of Mines. One of the most important studies that I had in hand in those days was in connection with the corundum industry of south-eastern Ontario.

That brings us close to one of the most interesting episodes in your life, I believe—the discovery of Cobalt.

I might say that when I became Provincial Geologist

I intended to hold the position for only about two years. I did not think that I would like Government work, but I thought it was a good opportunity.

To learn?

To get acquainted with the mineral resources of Ontario; in fact, I had leave of absence for only two years from Queen's University, but I had secured a good successor there in the person of Reginald W. Brock, who afterward became director of the Geological Survey of Canada, and by the time the two years had passed I was so interested in my duties that I stayed longer than I had intended.

You are still holding that position, are you not?

Yes.

Won't you proceed to describe the discovery of Cobalt, which, I believe, was the next important event in your life?

The Government of Ontario decided to build a railway from North Bay Junction, on the main line of the Canadian Pacific Railway, to Lake Temiskaming, to serve as an outlet for that agricultural region. During the construction of this railway, at a distance of 103 miles north of North Bay, some mineral deposits were discovered. There were no prospectors or miners in that region in those days.

Was there none in the crew working on the railway?

No, none. They were railroad men and nothing more. Late in the autumn of 1903 one of the men from that district brought a sample of ore to Toronto. He thought the sample was copper ore. It was the mineral niccolite, which resembles certain copper ores rather closely. When I saw the sample I knew that an interesting discovery had been made. I thought, of course, that it might indicate rich nickel deposits, as the well-known Sudbury area lies about 90 miles south-west of this locality, now known as Cobalt. As snow was likely to fall at any time in that latitude, it being late in the season—November—I hurried north, taking train to Mattawa, thence to the foot of Lake Temiskaming, and the steamer on to Haileybury, which is on the railway line, about five miles north of Cobalt. The steel had not been laid on the grade at that time, and the morning after our arrival I decided to go down to see the discovery. I walked along the grade, which was frozen, with a thin covering of snow, until I reached the place of discovery, which was on what came to be known as the La Rose mine.

Was there much ore showing in the railroad cutting, and what was the character of it?

No, it was on one side of the railroad, near the face of a cliff, at the bottom. A blacksmith employed on the right of way—named La Rose—had at one time worked in the phosphate deposits in Quebec and was more or less interested in minerals. He noticed this vein and when he had time he put a few shots in it. He evidently was after the 'copper', or niccolite, and was not taking much interest in the silver, for he blasted out some rich silver ore and threw it into the swamp.

Was there any native silver visible?

Yes, there was a lot of native silver; but the 'copper' was bright, and the silver was tarnished on the surface.

Did La Rose recognize the silver?

Apparently he knew it was silver, but he was not trying to save it, but was just blasting it out. Then there was a showing of silver in the bottom of a pit, the small opening that he had made. I got my pick under this and pried it up and got a piece about the size of my hand and about as thick. When I took that with me to Haileybury in the evening, the men there to whom I showed it began to get a little excited and decided to do some staking. Next day I went down to the discovery again, and I saw two or three other veins that had been found. One of these was a massive cobalt vein on what is now the Nipissing property. Another was on what afterward became known as the McKinley-Darragh, and the fourth was the most interesting vein discovered up to that time, or probably since. It was also on the Nipissing property, but the discoverer had not shown it to anyone. He was a Frenchman by the name of Hebert, who had been a professional strong man. The timber-cutters were at work on that area and Hebert was afraid that some of them might find his vein, so he took me to the place very cautiously. The vein was afterward called the Little Silver; it formed a fissure in the cliff, about 60 ft. high, and the face of the vein was weathered, leaving the silver exposed so that it was falling down the cliff. It was a real textbook vein.

Then the discoverers were not ordinary prospectors?

No; they were all employed in railway construction. La Rose was the blacksmith and Hebert was employed in some similar capacity, I don't know just what. He discovered some of these deposits by walking across to see a cousin, who, I think, was employed in cutting timber.

Then they had been in the employ of the railway construction company a few days before?

For some time; they were still employed. These discoveries were all within a few hundred yards of the railroad.

And all made within two or three days?

No; they had known of some of them for probably a month or two months, but hadn't paid much attention to them. I suppose they had never seen any ore before. La Rose had been working on phosphate, but I don't think he knew anything about metallic minerals.

Having made your inspection, what did you do?

I wrote to the Department, at Toronto, telling what I had seen.

Was that report published?

Yes. That letter was published with my subsequent report, I think. The result was that when I got out to the railway again the first thing I saw in the hotel was a large poster to the effect that the Government had withdrawn all the land for some distance along the railway, and for some distance on both sides—withdrawn

THE RAILWAY CUT IN WHICH THE MURRAY OREBODY WAS FOUND AT SUDBURY, ONTARIO

THE SHAFT-HOUSE OF THE CREIGHTON MINE, AT SUDBURY it from prospecting and staking. A few months later the land was again thrown open to location.

And the locations were validated?

Yes; the locations on which the discoveries had been made were recognized from the beginning. The Government didn't try to take them away. It was difficult to get the public interested in these deposits. Not long before that we had had a mining boom, one of our periodical booms in Canada, in which many people had lost money. The public had lost interest in mineral deposits. I had a good exhibit of these cobalt-silver ores placed in the King Edward hotel at Toronto, for the benefit of the Canadian Mining Institute meeting in March 1904, but nobody took much interest in it. They were fine specimens, but that was about all! It took nearly eighteen months to arouse public interest.

Since then how much silver has the Cobalt district produced?

Over 292,000,000 ounces, besides cobalt, nickel, and arsenic.

Have you remained Provincial Geologist and continued your interest in the exploration of this Canadian hinterland? Did you have anything to do, officially, with Porcupine, in its early stage of development?

The result of the success of Cobalt was that we got many prospectors into the northern country and many men who were willing to give financial support to small syndicates of prospectors. Every year since then, almost every few months, some important discoveries have been made. Until the railway was completed north to Cochrane, the Porcupine country and other areas were rather inaccessible, requiring a roundabout canoe trip to get there. The important discoveries at Porcupine were made in 1908, but not much work was done until 1909, when we placed a party in the field, to map the area. We have had parties surveying and mapping the surrounding areas ever since, each year. Porcupine has become widely known and Kirkland Lake, a district farther south, is now becoming an important producer. Gold has been found in promising quantities over a wide extent of country. In so far as the geology is concerned, Cobalt has served as the key to a wide region. Any person having a good knowledge of the geology of Cobalt has little difficulty in mapping other areas in the region.

Do you consider that there is a likelihood of further important discoveries in that part of Canada?

Yes, Sir; I expect that many important discoveries will be made there.

I presume that some valuable outcrops may be covered by the lakes and swamps.

Yes; the most important vein at Cobalt, for instance, lay under a lake. The latest gold deposit developed in that northern country, namely, the Lake Shore mine, on Kirkland lake, is similarly situated. That, by the way, is an interesting mine. It is opened up to a depth of about 400 ft., and the ore from development work has given a recovery of over $24 per ton.

From gold in quartz?

Gold in quartz.

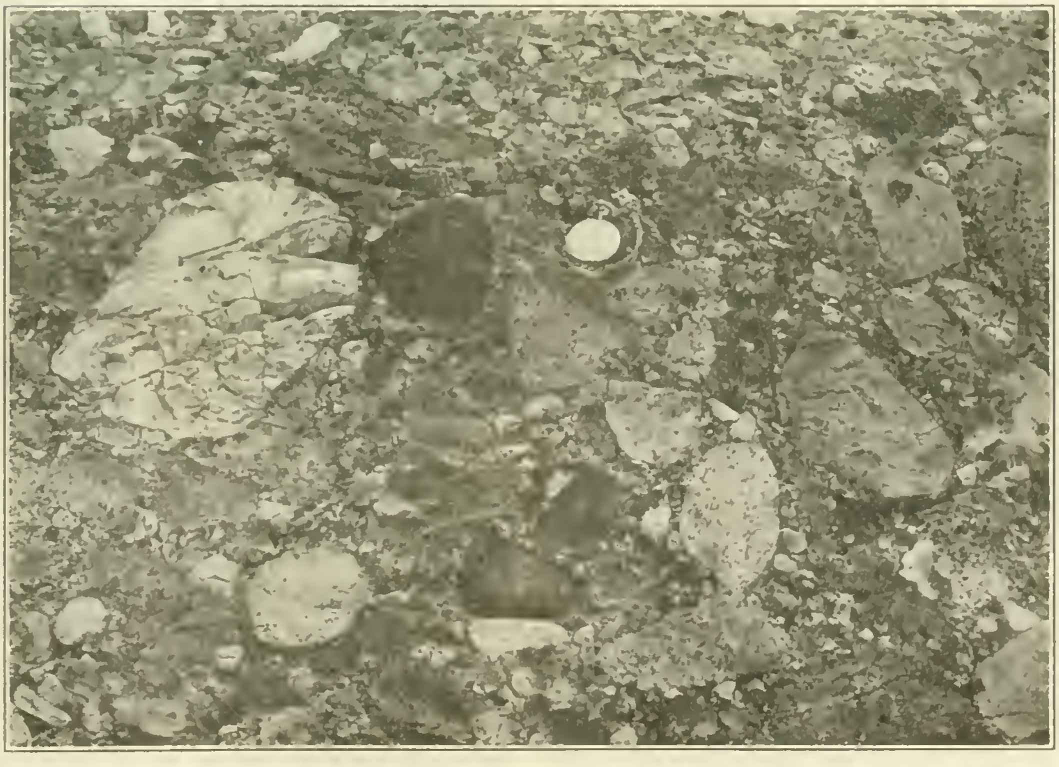
You have done a great deal of exploratory work in that part of Canada, and I should like to ask you to say something about the prospects generally, even outside Ontario, going so far as the Coppermine River district and Le Pas, in Manitoba. If you will be good enough to speak of the mining opportunities of this northern part of the continent I feel sure that what you say will be read with keen interest.

Canada has an area of about 3,750,000 square miles. About two-thirds of this area is occupied by pre-Cambrian rocks, and throughout these pre-Cambrian regions the conditions are much the same as they are in northern Ontario, where we have already proved that they contain important silver, gold, nickel, and copper deposits. We have great hopes therefore that many more Sudburies, Cobalts, and Porcupines will be discovered in these pre-Cambrian rocks. During the last three or four years important discoveries have been made in the provinces farther to the west, in Manitoba and Saskatchewan, for instance, the Flin Flon and Mandy lodes. The Canadian government has a railway nearly completed to Port Nelson, on Hudson's bay. The road is graded and I think only about 90 miles of steel remains to be laid. As soon as this railway is completed it will be possible for a prospector to take a boat on Hudson's bay and land on either the west or the east coast, where there are vast areas of promising mineral territory. I look on the regions around Hudson's bay, the pre-Cambrian shield, as it is sometimes called, as the most important prospecting ground, or unprospected territory, that remains anywhere in the world. While much of this big stretch of land is unprospected, the Canadian Geological Survey has had parties through these regions at various times, and we know what the character of the rock is. For instance, we know that the rocks in the Coppermine River region are much like those in the great copper belt of Michigan and we know that these Coppermine River rocks extend pretty close to the western shore of Hudson's bay. That country is, in many ways, easier to prospect than northern Ontario, because it has not such a growth of timber; it is more open. In some places, of course, it is low-lying, but elsewhere good exposures of rock are numerous. Then the east coast of Hudson's bay, which belongs to the Province of Quebec, is promising and has been prospected very little.

Why is that so?

Because this northern part of Quebec is difficult to reach by the St. Lawrence route. The rivers are rapid and difficult to navigate; but, as soon as we have some boats on Hudson's bay, the prospector will be able to get in and spend a good season there. The trouble with navigation there, of course, is in the straits; not in the bay itself. As you know, the Hudson Bay railway was built primarily to take grain from western Canada to Europe. I have always been in favor of building this road, not because I was particularly interested in grain,

COBALT IN 1911



THE CONGLOMERATE AT COBALT IN WHICH SILVER VEINS ARE FOUND but because it seemed to me that such a vast region should easily support one railway. There are fisheries in Hudson's bay that have not been examined thoroughly, but the mineral possibilities are the more attractive to you and me.

You must have found your work as Provincial Geologist deeply interesting, having regard to the evident progress made by Ontario in mining.

Yes, our mineral industry has had a marvelous growth since 1902. Our annual output, for instance, at that time was valued at about $14,000,000, whereas for 1918 it is over $94,000,000, according to the estimate of the Mines Department at Ottawa. The work, in addition to being interesting, has been pleasant, as I have always felt that I have had the friendship and support of the Ministers of Mines under whom I have served, notably the Hon. Frank Cochrane, who was Minister during the development of Cobalt. And our Deputy Minister of Mines T. W. Gibson, has always been my good friend. I have had opportunities to visit other countries during the period I have been Provincial Geologist, as the official representative of the Mines Department. I have made trips to many parts of the United States, and to old Mexico, to Cuba, to Great Britain, France, Scandinavia, Australia, and the South Pacific. Obviously, I was afforded unusual opportunities, for which I am grateful. Another thing that helped my work and made it pleasant was that I have had as my chief assistants former students of mine, from Queen's University, whom I knew thoroughly. Cyril W. Knight's work is well known in connection with Cobalt and other areas; so also that of A. G. Burrows. E. T. Corkill, one of my former students, was for a number of years Chief Inspector of Mines in Ontario, and is now superintendent of mines for the International Nickel Company, at Copper Cliff. Mr. Corkill was with us during the interesting developments at Cobalt.

Were any unusual difficulties settled during your time of service as Provincial Geologist? For instance, if I recall correctly, there was some complication over the Gillies Timber Limit.

When the Cobalt deposits were discovered the mining laws of Ontario were rather crude. The regulations had been devised more for taking up iron lands; they were not adapted to precious metal deposits. The result was that we had to spend much time in preparing the Mines Act and other legislative enactments. The regulations that we finally adopted included those for the discovery of the precious metals. As we officials had made the discoveries on the shore of Cobalt lake, I advised the Government to withdraw the lake from location. It also withdrew Kerr lake and afterward sold Cobalt lake for $1,085,000, deriving a large revenue from the Crown Reserve mine on Kerr lake. The Gillies Timber Limit adjoined the Cobalt area immediately to the south. It was withdrawn from staking in order to protect the timber. Finally, the Government itself decided to work this 'Limit'. I was put in charge. I did not believe that much would be discovered, however, as I had mapped the area in detail, but as the Government had decided on the policy I had to do the best I could. The Government was criticized a good deal by certain promoters, and prospectors kept constantly saying that if private individuals were working it a much greater success could be made of it. I quieted them to some extent by saying that I was "keeping a list of liars and lunatics who said they knew where there were rich veins on the Gillies limit." It is remarkable how many supposedly reputable citizens at that time solemnly affirmed that they had seen valuable deposits on the Limit! After working it for some time, I advised that we give these private individuals and companies an opportunity to work it. We then surveyed part of the Limit and put the claims up for sale by tender, the result being that the Government received a considerable sum of money; but no important discoveries have been made on it. I might add that, after the first sale, a discovery was made which created considerable excitement. Whereupon some of our newspapers said "I told you so" and "the Government did not handle this right," and so forth. I considered it quite a compliment to myself that when I immediately advised the Government to sell some more claims, it, despite the statements that were made in the press about the richness of the area, took my advice.

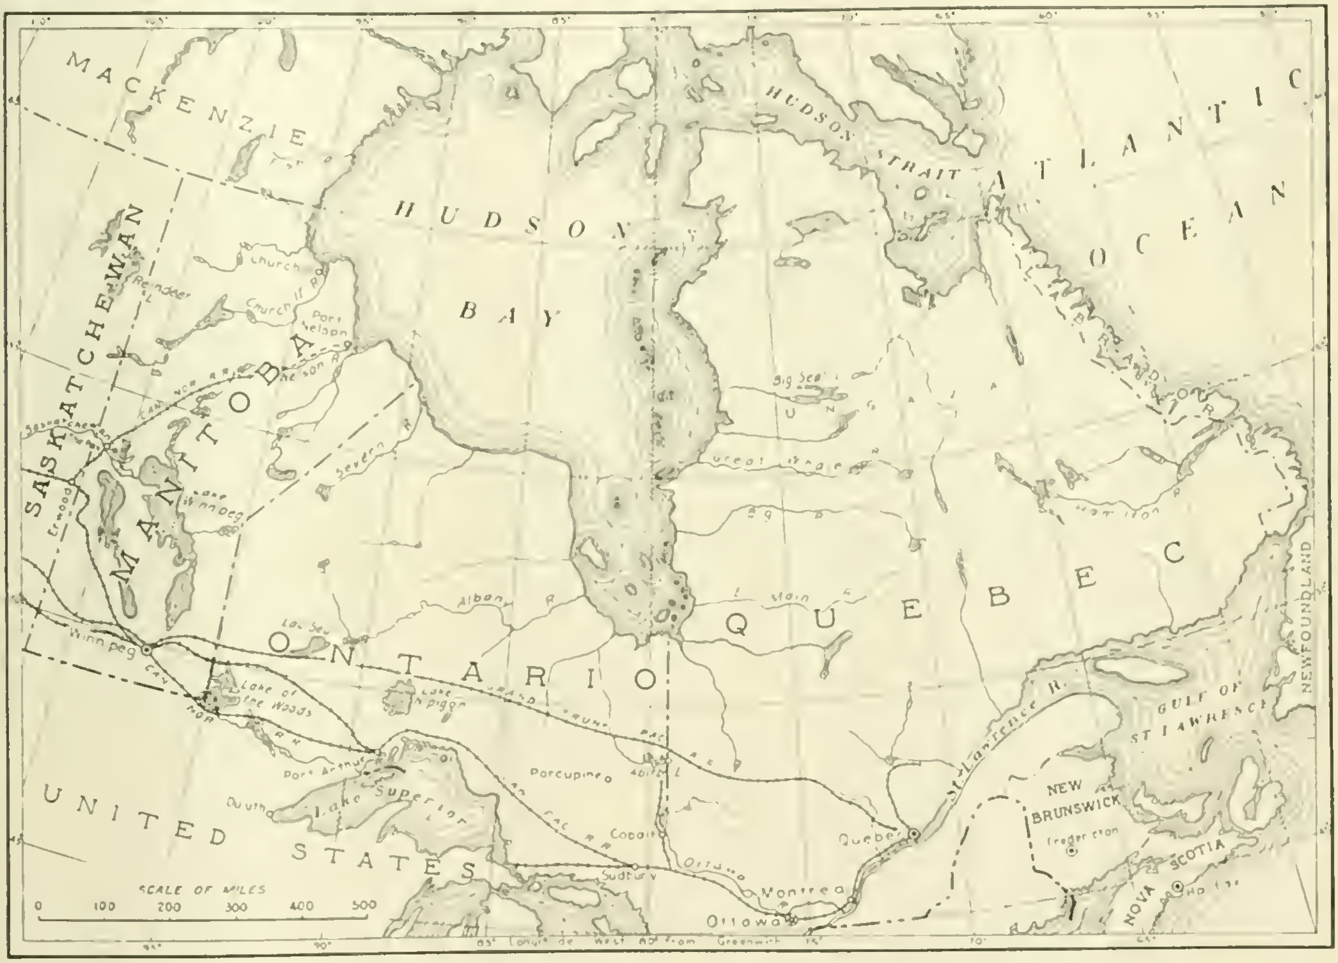
THE LAKE SHORE MINE ON KIRKLAND LAKE

You must have taken part in the efforts made to obtain the metals needed for the War? For instance, I might ask you to say something about the public feeling in Canada toward the American ownership of the nickel deposits at Sudbury and the friendly efforts made to adjust that difficulty.

Of course, when the War started our people naturally became a little nervous, or sensitive, as regards nickel, because, although we produced over 80% of the world's output, we were not refining any in Canada, and the public feared that some of our Canadian nickel might be getting to Germany.

There was considerable agitation on the subject, especially after the submarine 'Deutschland' was reported to have come to this side of the Atlantic to take back a cargo of nickel?

Yes; nickel has been a disturbing subject at different times in the past; there has been a public demand for the erection of a refinery in Canada. The result of the agitation during the War was that the Ontario government decided to appoint a commission, known as the Royal Ontario Nickel Commission, which consisted of the late George T. Holloway, metallurgist, of London, England, McGregor Young, legal adviser, T. W. Gibson, Deputy Minister of Mines, and myself. We were given authority to investigate the nickel industry of the world thoroughly. We carried on work in Canada, the United States, and in Great Britain. Some of us went to France, Norway, Cuba, Australia, New Caledonia, and elsewhere. This work took a year and a half, our report being published in 1917. We now have a large new refining plant at Port Colborne. This belongs to our biggest nickel-mining company, the International Nickel Company. The Mond Nickel Co., an English corporation, which is also working at Sudbury, refines its matte near Swansea, in Wales. The British-America Corporation, in which the British government is a large stockholder, is erecting a refinery near the city of Ottawa; so that within a comparatively short time Canada will not only be the principal miner of nickel, but a large refiner of the metal as well.



MAP SHOWING THE HUDSON'S BAY REGION

Does any of the matte go, as it did previously, to New Jersey?

Yes, the International Nickel Co. refines a large part of its matte in New Jersey, at the Orford works, near Bayonne.

How much do they refine in Canada?

Their plant in Canada started about the first of July 1918. The capacity of the plant at Port Colborne is 10,000 tons of nickel per annum, but in time the efficiency of the Port Colborne plant and double taxation may induce the company to do most of its refining in Canada. It is subject to taxation in both countries.

What are the prospects for the base-metal and precious-metal industries in Ontario at the present moment; that is, to what extent is the industry affected by the aftermath of war?

Our nickel output is not so large, but our gold output is expected to increase very much during the coming year. There has been a shortage of labor up to the present, but the mines are now getting all the men they need, I understand.

There is a confident feeling at Toronto, for example?

Yes, and I think this applies not only to Ontario, but to the more western provinces. British Columbia is optimistic. They have a large territory there to develop and their output has grown rapidly of late years. Then, on the eastern seaboard we have an important iron and steel industry and vast coal deposits.

Dr. Miller, I understand, from my own limited acquaintance with conditions in Ontario and British Columbia, for instance, that many of the mines are owned by American capitalists. May I ask you to what extent the use of American capital in these Canadian mining regions is welcomed by the people of the Dominion?

It is always welcome. I might say that in Canada we have no restrictions on aliens from the Allied countries like you have in the United States. I understand that in the United States an alien cannot stake a claim. We have no such restrictions in Canada. Anybody but an enemy-alien can locate a claim, just the same as the native-born. We expect to get a great deal of capital from the United States, and we expect to have a large immigration from the United States, too, into the mining districts and into the agricultural districts of the West.

There is a duty on machinery, and I understand that there is even a duty on blueprints. Is there any prospect of a removal of some of these commercial barbed-wire entanglements?

I suppose that will depend not only on Canada, but on the United States. Of course, the feeling between the two countries could not be better than it is. We Canadians always feel at home in the United States, and we believe that citizens of the United States feel at home in Canada. We, in geology, for instance, in mining, chemistry, and in most of the other sciences, work very closely with our friends in the United States. For example, in pre-Cambrian geology I have been closely associated at times with C. R. Van Hise and C. K. Leith, and with other geologists in the United States. During my lifetime I have noted that the friendly feelings between Canadians and Americans have grown and increased constantly. Our peoples have become more friendly as the years have gone by, and, of course, the War has intensified this good feeling. We think that while we live under different flags we have the same aspirations, and nothing can interfere with these friendly relations in the future. Canada stands probably mid-way between the United States and Great Britain in many things.

Have you any signs of labor trouble in Ontario?

No; we do not think we shall have any trouble at all.

What is your labor chiefly?

It has been pretty well mixed in the past. Some of it is foreign, but a high percentage is English-speaking.

You have been a prominent member of the Canadian Mining Institute and of the American Institute of Mining Engineers. Would you say anything about the good work that either or both of them are doing?

I think it is recognized everywhere that the American Institute is doing wonderfully good work, not only for the industry, but also for the profession. Its growth during recent years has been wonderful. The Canadian Mining Institute is a much smaller organization, but it exercises a good influence in Canada. The governments of the Dominion and of the Provinces have always been willing to listen to recommendations made by the Canadian Mining Institute, and it has served a national purpose.

What are the prospects for an increase of production in nickel and of the discovery of new deposits, in your opinion, based on your recent investigation of the subject?

The quantity of ore proved in the Sudbury district has increased greatly during late years. When the Nickel Commission's report was published I estimated the proved ore—the ore blocked out—to be at least 75,000,000 tons. Since then there has been a considerable addition to this tonnage at Sudbury.

The other important source of ore is New Caledonia, I presume?

Yes, but there are no known deposits elsewhere in the world that can compete with Sudbury.

Are those of New Caledonia approaching exhaustion?

No; there is considerable ore there yet, but it occurs under conditions different from Sudbury. The New Caledonian ore occurs in lateritic deposits. Some of the deposits at Sudbury are probably unsurpassed in importance in the world among deposits of any kind, when you consider their size and the value of the ore. Of course, the War has encouraged the use of nickel-steel and other alloys. This means increased consumption of nickel in the future. Many people have used nickel-steel during the War that did not know anything about it before. Likewise the metal cobalt, for which there was little market, has come into prominence through the War. Cobalt is used with chromium and tungsten in the production of an alloy known as 'stellite', which is an important high-speed tool-steel. This use of stellite has increased the demand for cobalt very much.

Did you have any particular experience while in England that you might care to recall?

During my last visit in England, in 1918, I was the Canadian representative on the Imperial Mineral Resources Bureau. The Imperial War Conference of 1917 decided to have such a bureau organized. Its work is to size up the mineral resources of the British empire. When the War started it was found that, while the Empire could produce certain ores and minerals, refining facilities were inadequate or lacking within the Empire for such ores. It was decided that this condition should not continue. The aim now is to render the Empire as independent as possible, particularly to make it independent of the German reduction works. Arrangements have been made for smelting Australian zinc ores in England and also in Australia. During the summer there was an exhibition held in London called the 'Key Industries'. This showed what great developments had been made in smelting and refining since the War began. Great Britain is now self-contained to a much greater extent than she was in 1914.

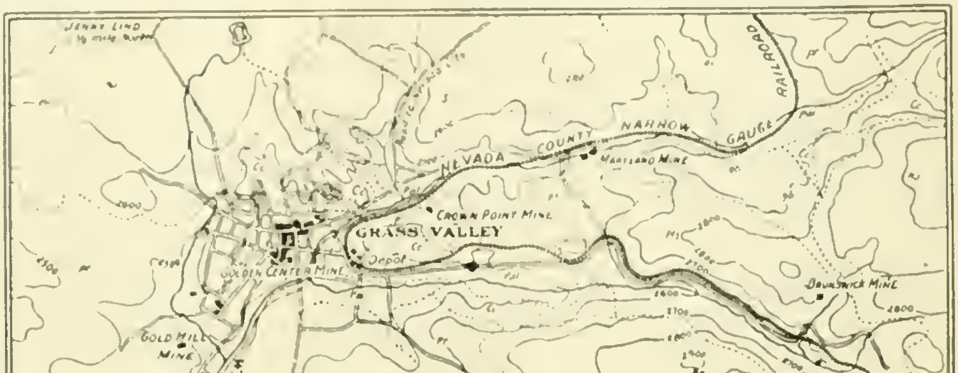
REVIEW OF MINING

GRASS VALLEY, CALIFORNIA

LAND TITLES IN DISPUTE.—RE-WORKING OLD PROPERTY.

The case of the Golden Center Mining Co. of Grass Valley v. the city of Grass Valley was partly heard in the Sacramento Land Office on May 21. The contest was ordered by the Secretary of the Interior on petition, and the issue to be determined is whether the Roche Rock quartz claim, within the city limits, sought to be patented by the plaintiff, was mineral land at the time of the issuance of the townsite patent in 1869 or not. The company attempted to prove that the ground had always been considered mineral bearing, while the city contended that this claim had been abandoned for years and was therefore worthless for mining purposes. The principal witness for the company, John E. Carter, swore that the mine was worked in a general way for about eight months in the early days, but operations were not profitable. Later attempts also resulted in failure. The company exhibited records to show a clear title to the ground, although at one time eight persons were rival claimants. The ground in dispute was located in 1916, and adjoins the Golden Center mine. Recent discoveries of ore in the latter ground, pitching toward the Roche claim, are the real cause of the contention. The Golden Center, in spite of irregular operation, is generally looked upon as promising, although not as extensively developed as its neighbors. A network of gold-bearing veins underlie the city, and should the issue between the plaintiff company and the city be upheld by the Department of the Interior, the entire townsite area will be located, and parties now await a favorable outcome in order to locate. Some of these prospective locations are governed by the same conditions as the case at issue. The city and immediate vicinity have become famous as a gold-producing area.

Another objection to the granting of a patent to the Roche Rock claim arises from civic pride at the behest of a few individuals who oppose mining within the residential district, and also to the precedent sought to be established, which may result in the upsetting of townsite titles. Aside from their own personal influence in opposing a patent, they prevailed upon the city trustees to oppose the granting of a patent. Compromise has been out of the question. Just where the city acquires the right to become a party in the adjudication of town titles is a problem, for the original patent was granted to the then judge of the County Court to be held in trust for the people and its successor, the present Superior Court. After the taking of testimony and hearing arguments the case was continued until June 20.



THE GRASS VALLEY DISTRICT, CALIFORNIA

A rich strike was made last week in the South Star mine in the Rough and Ready district four miles west of Grass Valley. A few men have been prospecting for several months under G. D. Freeborn.

A local co-partnership of 20 men, calling itself the State Highway Mining Co., until legally organized, has secured an option on the Morandi ranch of 200 acres a few miles south of town. Quartz veins were found in the early days and a small boom was in progress at one time. Revival of interest in that land was brought about by the recent discovery of specimen quartz by a member of a grading crew. Prospect holes from 30 to 40 ft. deep were sunk years ago, and some good ore extracted, yielding from a few dollars to $25 per ton, but no further interest was taken until recently. A gasoline hoist and pump have been installed on one shaft and two lots of men are at work preparatory to further operations. J. T. Blight is acting as manager and Fred Roehnert is secretary.

Dismantling of the machinery at the Idaho-Maryland is well advanced. The mill is gone, also the greater part of the plant around the hoist, all being shipped by rail to San Francisco.

The annual meeting of the Grass Valley Consolidated Mining Co., owner of the Allison Ranch mine, was held at Sacramento on May 24. Fair milling ore is coming from several upper levels and considerable prospecting is being done. A new board of directors was elected, namely: H. A. Heilbron, Sr., F. H. Buck, E. E. McMichael, A. E. Nelson, P. Huth, H. Kleisorge, Scott Ennis, and S. Jones. The board elected E. E. McMichael president, Scott Ennis vice-president, and H. A. Heilbron secretary-treasurer. C. A. Brockington will continue as superintendent.

HOUGHTON, MICHIGAN

IMPROVEMENTS AT THE QUINCY MINE AND MILL.

The Quincy company has completed the finest hoist-engine building in the Copper Country. Architecturally, it is admired by every visitor. It will house the most powerful hoist ever constructed—a new Nordberg engine that will pull a skip from a depth of 14,000 ft., the longest haul from any shaft in the world. The building was erected at a cost of $75,000. The interior finish is equal to the mine-office, yet the cost was not excessive, and includes the largest item, the concrete foundation for the engine. Erection of the hoist will require three, possibly four, months. It will serve No. 2 shaft, Quincy's deepest.

The Quincy mine is now yielding high-grade ore, the February production averaging 20 lb. (1%) per ton. This compares with 17.33 lb., the average for 1917. In March the yield was better than 19.5 lb. This includes a considerable quantity of mass copper. This is interesting, especially as the Quincy shafts all are very deep, and the yield of copper is higher than it has been at any time in ten years. It is indicative of the exclusion of the Pewabic lode from the general rule of the Lake Superior region that the copper content diminishes with depth. While mass and barrel copper continue to form an appreciable proportion of the Quincy output, the general run of ore at all of the newer openings is exceptionally good.

The company has instituted a scoop system to assist in stoping operations, which have become difficult in two of the shafts by reason of the flattening of the lode at great depth. This change in dip has prevented ore from dropping down the stope by gravity. A small 'puffer', operating a wide scoop, driven by an old wire hoisting-rope fixed along the roof of the stope, does the work successfully.

Quincy has the first stamp-mill with a plate-glass roof. Like the new hoisting-house at No. 2 shaft, the recent additions to the mill are very striking. The designs, in all cases, were made by engineering architects who knew nothing about stamp-mills or hoisting-plants. The glass roofs on the mill additions cost no more than the old style of roofing. They provide sunlight, saving electric light, and make the interior attractive for employees. The management contemplates the adoption of the glass-roof plan for the main sections of the mill, provided this experiment is successful, as seems likely. The additional mill capacity will probably increase the recovery from the milling ore by 4 or 5 lb. of copper, and reduce losses to a minimum.

An important source of copper was cut off by the Calumet & Hecla last week when the dredge that excavated sand from Torch lake went into dry dock for repairs. This shuts off 850,000 lb. per month. The boat has operated for five years. The plan to make extensive repairs was made more than a year ago, when the dock was built at Point Mills, five miles from the scene of dredge operations in Torch lake. The boat was towed through Torch lake and the canal into Big Portage to the specially constructed dry dock.

The exodus of workmen from the district has practically ended. No more men are being laid off by the C. & H., nor by its subsidiaries. The Quincy, Mohawk, Wolverine, and all three Copper Range mines—Baltic, Trimountain, and Champion—are working full time with full crews. Their copper output is not normal, but it has not been normal for more than a year. A limited number of the miners that were let out by the C. & H. and subsidiaries went to work at other mines in the district.

CHIHUAHUA, MEXICO

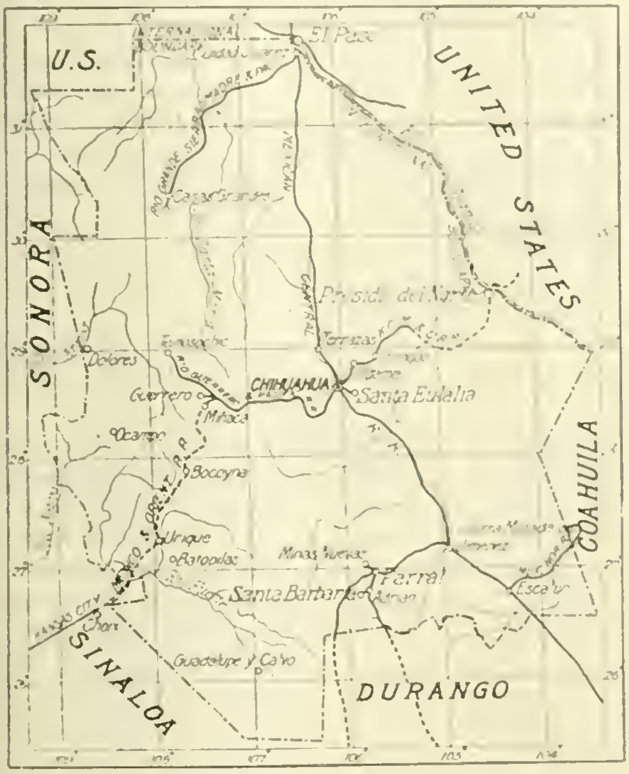
METAL PRODUCTION AND MINES IN OPERATION.

Fire recently destroyed most of the mining centre of Guadalupe y Calvo, near the border of Sinaloa, in southern Chihuahua. The nearest rail is at Parral.

For the first time since 1910 a complete statistical report of the mineral industry of Chihuahua has been compiled, giving the exact value of the mineral production for a whole year from all Chihuahua mines. The report was made by the State government.

The total value of metals from all mines in operation during 1918 amounted to P14,823,019. The value of the output in 1910 was P24,000,000. The principal companies that operated mines the past year were: The American Smelter & Refining Co., which produced P1,133,869; Potosi Mining, P5,629,605; Cusi Mining, P2,164,806; Buena Tierra Mining, P343,529; la Compania Minera de Lepanto, P95,951; Rio Plata Mining, P880,013; Mines & Metals Security, P85,624; la Compania Rodriquez Ramos, P864; Erupcion Mining, P134,364; Moctezuma Lead, P112,309; Alvarado Mining, Florencio Villegas and others, of Parral, P1,000,000. All tho companies whose names are not in Spanish are Amerean enterprises with the exception of the Lepanto, whose shareholders are Italians.

The location of the mines in operation in 1918 was at Sta. Eulalia, Villa Ahmada, Guazapares, Sta. Barbara, Parral, Almoloya (Jimenez) and Cusihuiriachic. The mines of Batopilas, Ocampo, Concheno, Dolores, Urique, Corralitos and Casas Grandes were not in operation during last year.



MAP OF STATE OF CHIHUAHUA

The following is a complete list of all the mining companies now working properties in Chihuahua, with the names of the mines and their location:

Dale Henos. y Co., the Inglaterra and the Emma at Sta. Eulalia.—Ing. Manuel Gameros, the Democracia, the Esmeralda, and the Plomosas, Sta. Eulalia.—San Toy Mining Co., the Galdiano, the Central and the Bustillos at Sta. Eulalia.—La Reina de Plata Ltd., the Las Contiguas de Sta. Fe, at Sta. Eulalia.—Buena Tierra Mining Co., the Buena Tierra, at Sta. Eulalia.—Potosi Mining Co., the Potosi and others at Sta. Eulalia.—American Smelting Co., the Sto. Domingo, at Sta. Eulalia.—Erupcion Mining Co., La Erupcion, at V. Gonzalez.—San Juan Mg. Co., the San Juan, at San Ignacio.—Rio de Plata Mg. Co., Sta. Barbara, the El Agua Novedad and the La Reina Felipinas, at Rio Plata.—Moctezuma Lead Co., the Alejandria, at Sta. Barbara.—San. Fco. Mines of Mex. Ld. Co., Varias proprietades, at San Fco. del Oro.—Comp. Metalurgica de Torreon, the San Diego, at Sta. Barbara.—Miguel Tinoco, El Calallo, at Sta. Barbara.—Florencio Villegas, the Clarines, at Sta. Barbara.—Carlos Villegas, La Cubana, at Sta. Barbara.—Alvarado Mng. Co., La Palomilla, at Parral.—Fco. Chavez (h), El Tajo, and the Ocho properties, at Parral. Cia. Igno Rodriguez Ramos, at Allende.—F. F. Herrera, El Hundido, at Villa Lopez.—The Cusi Mining Co., the Promontorio, at Ciro, and y Anexas de Ciro, at Cusihuiriachic.—And the Cusi Mexicana Mng. Co., the San Miguel, at Cusihuiriachic.

DURANGO, COLORADO

SILVERTON, RED MOUNTAIN, RICO, AND OURAY DISTRICTS.

No great activity is expected in the Red Mountain district until later in the season, when market conditions may be better, and operating costs lower. The rising price for copper is encouraging development of the local mines.

The Radiant M. & M. Co. has started development, and expects to be ready to ship in the near future, probably as soon as the Red Mountain branch of the railroad is opened.

Driving by the Summit Copper Co. is completed, the Kohler tunnel and the second level of the Carbon Lake shaft are connected by a 150-ft. raise, improving ventilation and cutting handling costs from the various levels to the railroad.

The Red Mountain Mines Co., has started another important opening, a cross-cut from the Joker tunnel to the lower shaft workings of the Robinson.

Driving continues in the Meldrum tunnel. This is being driven from the Red Mountain side of the range, starting at a point near Ironton, the Silver Bell mine, with the objective of connecting with the Bridal Veil basin on the Telluride side, from where a similar tunnel has been started. The distance to be driven is four miles; 1000 ft. of this has been covered on the Red Mountain side, and one mile has been driven from the Bridal Veil Basin side. The tunnels are 12 by 12 ft., and are expected to cut the extension of the Tomboy lode at a depth of 2000 ft. lower than the present workings. Several lodes are reported to have been cut on the Telluride side, affording encouragement for further exploration.

The rising price of metals has had a marked effect upon the development of the Rico district, and the outlook for a busy season is excellent.

A demand for the iron sulphides of the Marmatite M. & M. Co. resulted in that property resuming operations upon an extensive scale, and a large force has been employed on the Rico Argentine properties. Ore is now being shipped at the rate of 2 cars per day, and production will be increased. A mud-slide carried out part of the tramway and temporarily interfered with operations. Development of the bodies of iron pyrite continues, and shipments are going regularly to Eastern points. A large quantity of zinc ore is being mined.

Preliminary work at the Resolute has encouraged the operating company to complete the purchase price. Bonds will be issued to the amount of $75,000, to be secured by mortgages on the Newman group. This sum will be devoted to paying off the balance of the price of the property, and to building a mill with a flotation unit.

The companies at Ouray have adopted the Telluride scale of pay, with the increase to $1.35 per day rate for board. With the increasing price for silver, the various mines yielding such ore are encouraged to ship.

The Camp Bird continues to develop along the tunnel-level east, and there is a good showing of ore. No immediate change in the plans of blocking out 40,000 tons of ore in the mine stopes before resuming milling is to be expected.

The Atlas Mining Co. will continue to develop its holdings, and intends to operate upon a much larger scale during the present season. A better grade of ore is being opened and the financial condition of the company is excellent.

During discussion of the proposed reduction in wages, mining operations fell to a low ebb here, adding to the depression caused by the fire at the Sunnyside mine, but the outlook is somewhat improved, as the men have agreed to a reduction in wages, the rate to be $4.25 per day, a cut of 50c.; $1.25 is to be for board. The early agreement was due largely to the local spirit of co-operation that prevails. In the present dispute all interests endeavored to arrive at a mutual understanding. There is no question but that operators have been working on a small margin, due to well-known causes, and this point was conceded by the miners. The principal objection raised by the Union was the prevailing high prices of goods at the local stores, and as many of the men were obliged to maintain their families in town, and to board themselves at the mines, they questioned the fairness of an increase in the rate for board, while merchants maintained their prices. The storekeepers thereupon cut prices somewhat, offsetting the increased rate for board, and facilitating the settlement of the trouble. The labor situation is now settled, although Telluride has attracted a large number of skilled miners, left idle by the Sunnyside fire. Some months will probably elapse before the district is operating on a large scale, but the rise in silver and the gradually rising price of copper is encouraging, and will no doubt result in an earlier return to normal than anticipated.

An interesting item is the re-opening of the Gold Fountain property. This was located 20 years ago by O. C. Hand: related to a Chicago man, John M. Smyth, who invested a large amount of money in it, largely in tunnels and shafts. Upon Smyth's death operations came to a standstill. Although many applications were made for a lease on the property, the heirs of the estate refused, and held out for too high a price for a sale, so that the property has lain idle for a number of years. A company has been organized recently to operate the property under bond and lease, composed of heirs of the estate, and other residents of Delta, Colorado. A purchaser of shares in the new company is to take in addition a 1/50 portion of the treasury shares, paying thereon an assessment of 3 mills a share each month. The fund from these assessments is to be used for prospecting and development. Should much pay-ore be opened, assessments cease and the treasury shares become worth par. Officers are O. C. Hand, president; Dr. O. W. McArthur, vice-president; and N. J. Bradley, secretary

---

DIVIDE, NEVADA

LATEST DEVELOPMENTS.—NAMES OF SOME OF THE OUTSIDERS.

The Tonopah Divide last week sent 420 tons of ore to the MacNamara mill at Tonopah. Recent work includes driving raises for development of ore and improvement of ventilation, also cutting the station on the bottom level. On No. 3, the sill floor at 311 stope is in 45 ft., the ore averaging $85 per ton. No. 1 raise from No. 4 level is up 75 ft. in $60 ore. There are 38 men employed at the property.

The East Divide has cut a low-grade vein on the 400-ft. level. At latest advice the ore was 8 ft. wide, the other wall not being reached.

At the Gold Reef surface equipment is nearly complete. A motor-driven compressor and machine-drills have been put in. The shaft is down 115 feet.

The Dividend has replaced its gasoline machinery by electric motors. A station and pockets are to be cut at a depth of 500 ft., and the shaft sunk to 600 feet.

Other properties partly or fully equipped and at work include the Gold Reef Divide, Alto Divide, Sutherland Divide, Allied Divide, Rosetta, Gold Wedge, Ben Hur, Divide Annex, Verdi, Hennessy, Florence, Mohawk, East Divide Extension, Divide City Mining, High Divide, Victory, Crown, Western, Liberty, Calumet, Silver King, Syndicate, Trilby, Reno, Smuggler, Bevis, Pershing, Rand, Aztec, Old Timer, Hasbrouck Divide, Chariot, Kernick, Grimes, Silver Divide, Giant, Big Divide, Pyramid, Lookout, Goldsmith, Champion, Comstock, Wonder, Junior, Homestake, Mecca, Apex, Central, Doctor, Keystone, Western, Klondyke, Northwest, Portland, Charter, Ajax, Belmont, Bingo, Farrell, South, Telephone Girl, Ideal, Doughboy, Crescent, National, Sterling, Argentine, North, Wilson, Jim's, Mizpah, Kendall, Eureka, Treadwell, Gold Bank, Horseshoe, Marne, Sunbeam, Toggery, Mighty, Belcher, Operator, Midway, Rosalind, Emancipator, and many others.

The Emancipator is an enterprise of the Mudd, Webster, Wiseman syndicate, with W. C. Rannells, who managed the Hays-Monnette lease on the Goldfield Mohawk, in charge. The Kernick Divide, Giant Divide, Apex Divide, and Hercules Divide are Wingfield-Brougher companies; the Belcher and Victory are sponsored by officers of the Tonopah Belmont company; while the Argonne Divide, adjoining the Hercules and Rosetta, is headed by directors of the Tonopah Mining Company.

THE MINING SUMMARY

A bill to suspend all assessment work on mining claims during the War and for one year after peace is declared was introduced to Congress on May 31 by Representative Raker, and will be, it is reported, favorably considered by the House Mining Committee. The measure is important to veterans, inasmuch as many of the soldiers left their mining claims in California and other Western States to enter the Army, without performing their assessment work.

ALASKA

Anchorage.—The House Appropriation Committee at Washington decided on May 26 to include in the general deficiency bill an appropriation of $2,000,000 for immediate use in construction of the Government railroad in Alaska. Members of the Alaskan Engineering Commission said that construction would be interrupted unless money was provided soon by Congress. The Commission's request for an increase of the original $35,000,000 authorization for building the line, of which $31,000,000 has been spent, will be considered by the Committee in framing the new sundry civil appropriation bill.

Nome.—The ice on Bering Sea broke on May 27, a month earlier than last year, and the earliest since 1913

ARIZONA

Bisbee.—Shattuck Arizona Copper Co. during the first quarter of 1919 made a loss of $163,988. Revenue from metals, etc., was $227,520. The output was 1,000,844 lb. of copper, 678,914 lb. of lead, 160 oz. of gold, and 44,129 oz. of silver, from 11,831 tons of copper and 3138 tons of lead ore. Development amounted to 1708 ft. On the 200-ft. level there was opened 12 ft. of 7.2% copper ore for a length of 76 ft. Good oxide ore was exposed at 500 and between 700 and 800 ft. As fire broke out in the sulphide zone between 700 and 800 ft., mining was stopped on February 22. The workings were flooded and the fire was expected to be extinguished early in May. Tests are being made to improve the reduction of lead ore in the mill.

Jerome.—The United Verde Extension Mining Co. has been awarded by the State Corporation Commission a railroad freight rebate amounting to $200,000 on shipments of ore from Clarkdale to Globe and Douglas. The companies that have to pay this are the Southern Pacific, Santa Fe, El Paso & Southwestern, Arizona Eastern, and S. F. P. & P. lines.

Phoenix.—The Arizona Corporation Commission is to aid the State's copper companies in their protest against excessive freight-rates on copper bullion sent to refineries in the East. Before the War, the rate from Douglas to New York by way of Galveston was $8.55 per ton. Then came a raise of 25%, and later another that brought the rate up to the present figure of $16.50. It is estimated that, on the basis of normal bullion production, this means an added exaction of nearly $4,000,000 a year, to be paid by the Arizona companies. There is to be a hearing in Chicago on June 2, the complaint including 47 separate rail and steamship lines. Complainants are the Phelps Dodge, Calumet & Arizona, Old Dominion, and United Verde Extension companies. The Ray Consolidated has a separate action of its own.

Quartzsite.—At the Goodman gold mine a new mill is being erected, as the mine developed so well during the past year.

The Copper bottom mine, which had an excellent record up to a few years ago, is being re-opened by Chicago capital. Those in charge evidently are competent and financially able to bring this property back to its former good standing.

The King Placer Co. is negotiating for a new and larger steam-shovel to replace the one laid up.

There are two concentrating plants working on silver-lead ore at Dome. One crushes wet, using Wilfley tables; the other crushes dry, using Stebbins concentrators The dry process seems to give equal results with the wet tables on this ore.

Superior.—The Fortuna Consolidated Co. has been successfully financed, and sinking is to be started at once on the most favorable showing developed in the tunnel recently driven. A hoist and compressor are to be installed

CALIFORNIA

Pala.—Lepidolite, a silicate of alumina and potash, is found in small quantities in many localities in this country, but the only known deposit of commercial size is at this place in San Diego county. A mine there is operated by the American Lithia & Chemical Co., of New York.

Portola.—The Anaconda Copper Mining Co., of Montana, which controls the International Smelting Co., has the following statement in its report for 1918, just issued:

Walker Mining Company—On October 1, 1918, the International Smelting Co. exercised its option on 630,000 out of a total of 1,250,000 shares of the Walker Mining Co.'s stock. This property is in Plumas county, California, 22 miles by wagon-road from Portola, a station on the Western Pacific railroad The holdings of the Walker company consist of 38 patented lode claims and 2 placer claims, all forming a compact block of ground. The exploration of the property to the depth of 346 ft. has been accomplished by two shafts Drifts from these shafts have opened an ore-body 800 ft. long averaging 16 ft. wide, and a grade of 4% copper. Recent developments by means of diamond-drill holes indicate an additional length of vein approximating 900 ft. There is still a considerable amount of unexplored ground. The following construction and development program is now in progress: (1) Increasing capacity of concentrator to 200 tons per day; (2) construction of a new tailing dam; (3) erection of an aerial tram 8.2 miles long to carry concentrates to and supplies from the railroad; (4) driving a cross-cut tunnel from the concentrator site a distance of 3500 ft. to strike the extension of the vein, then following the vein to the shaft, a distance of 1200 (this tunnel will develop the property to a depth of 800 ft.) (5) additional housing facilities for employees; and (6) additional equipment in the form of electric hoist and small shops.

Washington.—R. E. Conrad, manager of the Sierra asbestos mine, a short distace from town, is preparing to resume work for the season. Mining was discontinued last fall because it was impossible to dress the rock except by the dry process. Mining is by open-cut.

John L. Whitney, superintendent of the Columbia mines at Ormonde, has 10 men at work, and the 20-stamp mill will be started this week.

Thirty men are employed at the Gaston mine and ore is being extracted from the lower tunnel.

COLORADO

Boulder.—The City Bank & Trust Company's business at Denver was suspended on May 28, by order of the State Bank Examiner, Grant McFerson. According to W. J. Galligan, president of the institution, and George McLean, vice-president, a cashier named R. A. Brown and an assistant cashier named P. A. Simpson, and J. S. Barnhill, president of the Colorado Pitchblende Co., a depositor, figured in the transactions that caused the trouble. It is alleged that the cashiers mentioned accepted Barnhill's drafts on a bank at Burleigh, Idaho, and issued cashier's checks in return. The president of the bank had given orders that no money be loaned to Barnhill, but apparently the cashiers did so by irregular methods. Brown disappeared early in May, sending in his resignation. Simpson confessed what had been going on. Detectives were searching for Brown and Barnhill at the end of May. The secretary of the Colorado Pitchblende Co. said that all attempts to find Barnhill up to May 29 had been fruitless.

Cripple Creek.—According to D. C. Wannamaker, secretary of the Cripple Creek Mine Owners and Operators Association, while a number of miners have returned to the district and been given employment in the past three weeks, there is still need of 75 to 100 experienced machine-men and shovelers. Machine-men receive $4.50 and the shovelers $3.75 per day. Mr. Wannamaker states that there has been more demand for properties for leasing in the past month than for several years, and that a number of properties will start as soon as an ample supply of labor is

The Cripple Creek District Commercial and Auto Club has appointed a committee to wait on the mine-owners to see if they will make concessions on the rates of royalties and thereby encourage a lot of surface prospecting and other mine development, especially during the summer months.

The Vindicator has added four concentrators to its flotation plant.

IDAHO

Lenia.—The Idaho Gold & Ruby Mining Co. in Boundary county will have its 6-mile ditch completed in two months, according to the president, J. M. Schnatterly. Sluice-boxes are being built. Three 9-inch nozzles will be used to move the gravel.

Mullan.—The Federal Mining & Smelting Co., which operates the Morning mine and mill at Mullan, the Standard-Mammoth and Greenhill-Cleveland mines and mill at Mace, and the North Star-Triumph and Independence mines and mill at Hailey, reports gross sales of $2,405,867 during 1918. The profit was $545,876 plus $296,382 from other sources, a total of $824,258. Dividends amounted to $838,854. After paying for miscellaneous charges there was a deficit of $108,917. Cash at the end of the year was $285,440, against $1,601,157 on December 31, 1917. Settlement with the Minerals Separation company is placed at $142,536.

The Rex Consolidated is to resume work when prices are normal, and sink its shaft 400 ft. to 1100 ft. depth. The company has acquired an interest in a copper mine near Cima, California. Recently a good deal of its Idaho mine equipment was stolen.

MICHIGAN

Houghton.—Copper Range pays 50 cents per share on June 16. This is equal to $197,199 and makes $591,598 for the current year and $26,012,302 to date.

Wolverine pays 50 cents per share on July 1. This is equal to $30,000.

NEVADA

Elko.—The new Catlin 150-ton oil-shale plant is in operation, in charge of Walter Sheeler. There are 40 men employed at present.

Fallon.—The Travelers Oil & Development Co. has been organized by commercial travelers for the purpose of exploring the Linder oilfield in the Stillwater district, 20 miles east of Fallon. The field was recently examined by N. R Garlims, who pronounced the geological indications indentical with those prevalent in the Coalinga, Fullerton, and Lost Hills fields of California. Preparations are being made to start a drill at the most promising point, where the shale yields traces of oil.

Jarbidge.—The Coeur d'Alene-Jarbidge Gold Mining Co was organized under the laws of Idaho in 1910 to work the Victoria group of 11 claims. This property covered about half of the floor of Jack Creek crater, at an elevation of 8000 to 10,500 ft. Over $5000 was spent in development. Unfortunately, an empty treasury late in 1916 caused the company to forfeit its claims on January 4, 1917. The ground was immediately re-located, when 17 claims were staked, now known as the Bullion group. The new owners, A. L. Rinearson, V. M. and N. N. Vuckovich, have uncovered four new veins, the largest being 16 ft. between smooth walls. Hand samples show free gold. The old company had opened three veins, each 40 to 48 in. wide. Two of them contained ore that paid to sack. The intention was to pack the ore 4 miles down Jack creek to the wagon-road, then haul to Rogerson, Idaho, for shipment by rail to a smelter.

Isaac W. Anderson of Tacoma, Washington, was at Twin Falls, Idaho, recently when, it is said, he obtained a lease and option to purchase the Bluster mine and mill for Spokane capital.——It is also reported that George Wingfield has secured a lease and option to purchase the Success mine. The Success adjoins the Bluster on its north end. He had a previous option on the Success, but gave it up.

Reno.—The Star of the West Mining Co. has recently been incorporated and taken over the property formerly belonging to an English company, called the Nevada Mining Co. The mine is on the northern line of Nye county and consists of three patented claims and mill-sites. The property was tied up by litigation for years, preventing operations; but prior to that time it is stated that the owners produced more than a million dollars of gold and silver. More than a mile of underground development work has been done, and the deepest working is only 170 ft., with veins intact at that point, and the value ranging from $10 to $50 per ton. The old mills on the property are obsolete, and this company has purchased a mill from the Colorado Iron Works of Denver, one that will treat about 50 tons of ore per day, as a first unit of a larger plant. As soon as the weather permits, erection of the mill will be started.

Round Mountain.—The report of the Round Mountain Mining Co., Gibson Berry superintendent, for 1918, contains the following:

Placer gold realized $68,324, and sundry earnings brought the year's total to $98,889. Operations cost $74,245, leaving a profit of $24,646. Current assets total $100,356 and liabilities $82,886. The cost statements are given in great detail. In the lode mine, lessees performed 2292 ft. of new work and restored 1033 ft. of levels, and resulted in the company getting $19,657 in royalties. They mined 2131 tons of ore averaging $36.70 per ton. This was reduced by Huntington and tube-mills in the company's own plant. In the placer mine, the season for water was poor, giving hydraulic head for only 1318 hours, against 2928 hours in 1917. Normally there is enough water for two giants, but last year there was not sufficient for one. The current season of 1919 had the greatest snowfall ever known in the district, and it is estimated that 200,000 yards of over $1 gravel will be moved, compared with 71,367 yards of 95.7-cent material in 1918. The operating cost was 68.35 cents per yard. The Star drilling-rig worked ahead of hydraulicking, and 600,000 cu. yd has been sampled, averaging over $1 per yard.

UTAH

Alta.—Snow has been moved from the railway into the Cottonwood district, and ore is now being sent to market. In places, the snow was 15 ft. deep. Shay engines are used.

The Wasatch Mines Company's tunnel is in 4200 ft., and another 160 ft. is expected to reach the Rexall-Cardiff fault-plane, on which the Wasatch vein, in No. 5 stope, developed much rich ore above until the large volume of water prevented profitable extraction. When this objective is reached, the workings will be at a vertical depth of 575 ft and the tunnel will permanently overcome all difficulties with water. During April the tunnel was advanced 222 ft. Progress is at the rate of from 7 to 10 ft. per day, with two shifts engaged.

American Fork.—Five mines are now at work in this district, the higher price for silver making the outlook more attractive.

Eureka.—The Chief Consolidated, Cecil Fitch superintendent, has issued a report covering the first quarter of 1918. The net profit was $125,304. Dividends—12½ and 6½ cents—in February and May absorbed $168,004, making $1,402.875 to date. Current assets total $243,895, plus $505,504 in Liberty Bonds and $76,336 in cash. Liabilities amount to $82,456, plus $134,120 for taxes. New work in the mines covered 5070 ft., on the 1000, 1600, 1800, and 1900-ft. levels. The most important result was the discovery of ore on the 1052 drift, which has been prospecting ground 3000 ft. east from No. 1 mine. This is regarded as a new ore-channel. No. 2 shaft, being sunk, will serve as an outlet for this ore. Shipments were 15,170 tons of ore averaging 0.0406 oz. gold, 38.427 oz. silver, 9.23% lead in lead ore and 1.46% copper in copper ore. The gross value was $43.57 per ton. All costs were $35.30 per ton.

Morrissey.—The Utah Sulphur Co. in Beaver county has decided to construct furnaces for the subliming of sulphur, according to M. P. Morrissey, general manager. Improvements are estimated to cost $180,000. When the additions are complete the works will have a daily capacity of 600 tons of ore, yielding 150 to 200 tons of sublimed sulphur. Some sulphur disulphide will be made also. The two retorts in operation are making 40 tons of high-grade sulphur per day and the output has been sold for 60 days.

Park City.—The Silver King Coalition Mines Co. during 1918 received $797,181 from the sales of ore, etc. Of this, $97,651 was profit, less $51,602 for depreciation. Dividends absorbed $182,415, so the surplus was reduced by $136,365. In the mine, development covered 7143 ft. The output of crude ore was 8184 tons of first-class, assaying 32.72% lead, 28.42 oz. silver, 0.08 oz. gold, and 0.296% copper. Concentrate from 43,042 tons of ore carried 24.3%, 19.92 oz., 0.066 oz., and 0.235%, of these metals. The total output was 10,105,775 lb. of lead, 440,064 oz. of silver, 1375 oz. of gold, and 109,732 lb. of copper. During April, 1919, the 1300-ft. level is opening some important orebodies. S. A. Knowles is superintendent.

Silver City.—G. H. Dern has transfered his interest in the Tintic Milling Co. to Jesse Knight, who has been associated with him during the past four years. The daily capacity of the plant is 150 tons. T. P. Holt is superintendent.

Tintic.—On May 18, the miners on strike here decided to vote on the dispute on the 20th, but a meeting of 1200 men on the 19th voted to defer action until some later date.

The Tintic Bullion Mining Co. has been organized by J. M. Bestelmeyer and others to develop property adjoining the Eureka Bullion and other claims in the East Tintic district. The capital is 1,250,000 shares, 5 cents par.

WASHINGTON

Keller.—All of the machinery for the Addison Mining Co. has been delivered at the mine on Silver creek, near here. This is the largest plant and the most valuable addition to this district in many years.

Loon Lake.—The Loon Lake Copper Co.'s new mill has been started. Some high-grade bornite was recently opened on the 200-ft. level.

Oroville.—The Okanogan Power Co. is to construct a dam on the Similkameen river, also a 2000-hp. generator, 3½ miles from Oroville. While the primary consumption of power will be for irrigating purposes, the mines will have all they need.

Republic.—Lessees at the Ben Hur mine have driven an adit 45 ft. and cut a 2-ft. vein. Face samples assay from $10.50 to $25 per ton. They have built a tramway from the mine bin to deliver ore direct to railroad cars, and have shipped the first 50 tons of ore.

W. G. C. Lanskail, the lessee, has men extracting ore from the bottom level of the Quilp mine, at a depth of 800 ft. That level is 100 ft. deeper than where J. L. Harper stopped work on the same ore-shoot. The ore averages $16 per ton, mainly in gold. The first carload was shipped a week ago.

It is reported that a rich shoot was found in the bottom level of the Knob Hill mine a few days ago.

CANADA

British Columbia

Anyox.—The Granby Consolidated has announced another advance in wages. It amounts to 50 cents per day to miners and 25 cents to smeltermen and others; 1200 men are affected. This is in addition to a 25-cent raise for every 2-cent increase in the selling price of copper. Wages have been increased about $1 since April 1, when the plant was re-opened after being suspended for 30 days.

The Dolly Varden property, one of the most promising silver properties in the Alice Arm district, is expected to be taken over by the Taylor Engineering Co. This concern constructed a railway from the coast to the mine, which also serves a number of other good prospects. The Dolly Varden company failed to pay the Engineering company all that was claimed for this work and, by an act passed at the last session of the Provincial Legislature, the Dolly Varden and the Temiskaming Mining Co. of Ontario were given until May 19 to take care of claims amounting to $462,500. This they have not done apparently, and the Taylor company, therefore, has the power to take possession, its first responsibility on doing so being the discharge of wages due workmen amounting to about $150,000. This done, the same concern has authority to proceed with the operation of the mine.

According to reliable information, representatives of the Dolly Varden Mining Co. intend to appeal to the Dominion government for the disallowance of the Provincial legislation that gives the Taylor Engineering Co. power to take over the mine and other of the company's holdings in order to satisfy claims it has presented in respect of the construction of the railway from Alice Arm to the mine. It already has been reported that the time given the Dolly Varden company to meet the financial terms laid down by the Legislature has lapsed, and that the Taylor company is proceeding to take possession.

Hazelton.—Work was resumed at the Silver Standard property, Glen mountain, Omineca, on May 1. This is one of the largest producers of silver-lead-zinc ore in northern

British Columbia. Satisfactory arrangements have been made regarding freight-rates and treatment of concentrate at the smelter, etc. W. G. Norrie-Loewenthal is manager.

Nelson.—The properties in this mining division are mainly of the free-milling gold type. Many of them are idle, partly due to poor management in the past, and partly due to lack of capital and development. Those mines that the Consolidated M. & S. Co. of Trail acquired have been entirely satisfactory. It is certain that the idle mines could be purchased at low prices and on good terms.

A meeting of the Nelson, Slocan, and Eastern British Columbia Mining Associations was held here recently. Preliminary arrangements were made for the International Convention to take place on June 19, 20, and 21 at Nelson. An organization was appointed to prepare for the gathering, the personal of which is as follows: Hon. W. Slocan, Minister of Mines, honorary president; S. S. Fowler of Riondel, Sidney Norman of Spokane, Frank C. Bailey of Spokane, and A. B. Trite of Fernie, honorary vice-presidents; J. J. Malone of Nelson, president; W. A. Cameron of Rambler, A. N. Wallinger of Cranbrook, Fred J. Peters of Rossland, Alex. McCrea of Revelstoke, J. R. Hunter of Nelson, J. D. Blackwood of Nelson, and J. E. Thompson, vice-presidents; Fred A. Starkey of Nelson, secretary; J. A. Gilker of Nelson, treasurer; A. G. Larsen of Spokane, M. M. McCune, Sheep Creek, E. W. Widdowson, Nelson, I. G. Nelson, Nelson, and C. F. Caldwell, Kaslo, directors.

Salmo.—The Sheep Creek mining district was first opened in 1894, the date of staking the Yellowstone claim by Thomas Bennett of Ymir. The Aspen, Emerald, Hudson Bay, and Jersey contain silver, lead, and zinc; and the Ore Hill, Spokane, and Summit, gold, silver, and lead, the remainder of the groups yielding free-milling gold ore. The Mother Lode has a cyanide mill, 20 stamps are on the Queen-Yellowstone, and 4 stamps on the Nugget. There are some promising claims here held by prospectors, also some vacant land worth-while.

Silverton.—At a recent meeting of the Silverton Miners' Union it was decided to endeavor to obtain a six-hour shift as a day's work, at the rate of $1 an hour.

Stewart.—The revival and opening of silver mines in the Salmon River district, north of this place, has resulted in Stewart having a newspaper, the 'Cassiar News'. It is published in the interests of Salmon River, Portland Canal, Alice Arm, and the Anyox mining districts.

Ymir.—This district is in the Nelson mining division of west Kootenay. Its area is about 144 sq. miles. Eleven creeks flow into the Salmon river from different points. There are 300 claims staked, a good many held by prospectors, and a fair number of promise. The Yankee Girl is the only one at work. The ores mostly carry gold, although a few have silver, lead, and zinc. There is said to be lots of vacant ground for prospecting.

Ontario

Cobalt.—The Mining Corporation is to diamond-drill the contact that passes north-westerly through the south-eastern part of Buck township, two miles from Cobalt. The contact is assumed to be at a depth of 300 feet.

The Nipissing company in April produced silver worth $219,927 from 6512 tons of ore. The refinery shipped 301,458 oz. of silver. Developments generally were favorable. Vein 99 had been opened for 50 ft., showing 1 in. of 1000-oz. ore; and a winze down 50 ft. opened 1 in. of rich ore, alongside of which was a ½ in. of matted wire silver. On vein 109, over 130 ft. of driving showed 2 in. of 3000-oz. ore.

Porcupine.—The town of South Porcupine had a disastrous fire on the 15th whereby 20 buildings were destroyed.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

H. C. Colburn, of Denver, is here.

Richard A. Parker is in New York.

E. W. Engelmann is now at Hayden, Arizona.

T. J. Jones sailed for Vladivostok on May 25.

T. H. Jenks, of Phoenix, Arizona, is at the Chancellor Hotel.

John A. Rice has returned to San Francisco from Cananea, Mexico.

Samuel H. Dolbear has gone to New York. He will be away for a month.

A. H. Richards has been promoted to superintendent of the Garfield smelter.

C. B. Brodigan has been appointed manager of the Brakpan mine in the Transvaal.

Clarence Woods is examining silver mines near Hermosillo, in Sonora, Mexico.

Edwin J. Collins, of Duluth, has been examining a copper property in the Ray district of Arizona.

Stewart L. Rawlings, general manager for the Cerro de Pasco, has arrived in New York from Peru.

J. T. Reeder has resigned after 30 years service as one of the Calumet & Hecla purchasing agents.

Ralph Arnold, who has been working for the U. S. Bureau of Internal Revenue, is returning to private practice.

A. J. Walton, manager of the Rose Deep, has been appointed manager of the Crown Mines, at Johannesburg.

Arthur S. Dwight, Major in the 11th Engineers, has been awarded the D. S. O. by the British military command.

L. C. Graton has taken charge of the copper division of the Industrial Unit of the U. S. Bureau of Internal Revenue.

A. H. Burroughs, Jr., has become associated, as mining engineer, with **H. H. Armstead**, and has gone to Talache, Idaho.

Charles McKinnis, manager for the National Copper Co., at Wallace, Idaho, has taken a lease in the Ranger oilfield in Texas.

Fred E. Carroll, State Commissioner of Mines for Colorado, has resigned to devote his time to mining interests in the Ouray district. He was Commissioner for four years.

Harry E. Nelson has opened an office in the Hollingsworth building, Los Angeles, where he will specialize in the design of treatment plants, particularly the crushing department.

L. H. Goodwin of 42 Broadway, New York, has left for an extended scouting trip through the principle silver-mining districts of the Western States and Canada, the work being undertaken for the firm of Rogers, Mayer & Ball.

R. S. Baverstock, of Baverstock & Payne, has returned from Trona, California, where he has completed the installation of a 30-ton Gibson mill and cyanide plant for the Stockwell Gold Mining Syndicate of Los Angeles.

William A. Daly, general superintendent of the mines of the Anaconda Copper Mining Co., has been promoted to assistant manager of mines, taking the post made vacant by the resignation of **B. H. Dunshee** last August. **Chauncey L. Berrien** has been advanced to general superintendent

The Utah Society of Engineers held its annual banquet at Salt Lake City on May 21. The presidential address was given by Leonard Cahoon. The membership is now 211, an increase of 38 during the year 1918-'19. The net resources of the Society are $1729.

THE METAL MARKET

METAL PRICES

San Francisco, June 3

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8.50
Copper, electrolytic, cents per pound	16.50
Lead, pig, cents per pound	5¼—6½
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce	$115
Quicksilver, per flask of 75 lb	$95
Spelter, cents per pound	7½
Zinc-dust, cents per pound	10—12

Nickel is 40 cents a pound. During 1918, the International Nickel Co. made a net profit of $5,922,630, after allowing for all charges. Dividends were $534,756 (6%) on preferred shares and $4,183,460 (10%) on common shares. Current assets are $12,969,589 and liabilities $3,708,902. There was $3,180,210 spent on new plant and property. Everything is in good physical condition.

EASTERN METAL MARKET

(By wire from New York)

June 3.—Copper is quiet but steady. Lead is dull and easier. Spelter is inactive and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May, 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

According to John D. Ryan, of the Anaconda company, which produced nearly 11,000,000 oz. last year, silver prices will remain high for several years and have not yet touched their highest level.

Writing on May 8, Samuel Montagu & Co., of London, say that although two days have elapsed since the United States removed restrictions on silver, control, at the time of 'fixing', on that date, had not been removed from the London market. Business meanwhile is in absolute suspense, as the London quotations, calculated as they are upon the now fictitious basis of 101½ cents, have no relation whatever to the actual value of silver. The Shanghai exchange has risen to 5s. ½d. ($1.21) the tael. Owing to activity of the Indian export trade, the Indian Council recommenced offering remittances for tender. The amount thus dealt with on May 8 was 60 lacs ($1,920,000). A similar amount was to be put up for tender the next week. About a thousand more lacs of silver is held in the note reserves than on October 15, the last occasion when tenders were solicited.

According to John D. Ryan, of the Anaconda company, which produced 304,000,000 lb. last year, copper is in better position than for many months, but its future will depend on the restoration of European industry to pre-war prosperity. There can be no marked advance in the price of the metal until the European demand revives.

E. H. Gary, of the U. S. Steel Corporation, in commenting on the improving conditions in the iron and steel business, considered that 20-cent copper was probable.

The copper embargo on imports into France has been lifted.

LEAD

Lead is quoted in cents per pound, New York delivery.

Eastern Metal Market

New York, May 28.

There is less activity in all the markets, but price changes are absent and quotations firm.

Antimony prices are higher.

Copper demand has slackened decidedly, but prices are firm and unchanged.

Lead buying has declined, but the market is firm and strong.

Tin is stagnant and somewhat staggered by the report of the authorities on the tin supplies of the country.

Zinc market continues inactive, with prices steady.

ANTIMONY

The market is stronger and higher. Wholesale lots for early delivery, New York, duty paid, are quoted at 8.25 to 8.37½c. The metal is in strong hands.

ALUMINUM

For No. 1 virgin metal, 98 to 99% pure, the quotation is 32 to 33c. per pound for wholesale lots for early delivery.

COPPER

The activity that characterized the market for a week or 10 days has subsided. It gradually gave place to moderate buying about a week ago or late last week. Today the market is quiet but prices are firm, with electrolytic copper held at 16.50 to 16.75c., New York, for June-July delivery, with 17c. asked for August. A few producers are taking a little business at 16.37½c., New York. For delivery beyond July most of the large producers are extremely shy about selling, and are stiff in their ideas of prices, not less than 17c. being considered. The recent buying movement, which has subsided somewhat, represents a distributed consumption. Some producers are sold up for June delivery. The purchasing is distinctly analagous in its character to that which took place late in March or early in April. At that time consumers filled their needs well into May. On this movement they have satisfied their requirements possibly through July, and this is probably the reason for the quieter tone. The volume, howover, was much larger this month than in the earlier period referred to. Export business is reported as better but not significant yet. Lake copper is quoted at 16.75 to 17c. for June-July delivery, with demand good.

IRON AND STEEL

Sentiment in the trade is generally better and demand for steel has improved. Predictions of lower prices are less frequent or confident; recent quotations are generally being maintained, and makers have generally been firmer than buyers expected. Ten large automobile companies have signed contracts for billets, sheets, wire tubes, all totaling over 300,000 tons. Another motor maker is in the market for a large tonnage. More buyers have come into the market in the past 10 days for contracts running for 60 to 90 days as against former hand-to-mouth buying. The rail order for 200,000 tons was distributed among six companies at $47 per ton for open-hearth. A decision is announced to reinstate on car-builder books some 20,000 cars for France, reinforcing the better tone.

LEAD

The market has turned quiet after the decidedly large volume of business done a week ago. Late last week a premium was realized in the outside market running as high as 5.37½c., New York, but these have disappeared and the market has settled down to the American Smelting & Refining Co.'s quotation of 5.25c., New York, or 5c., St. Louis, for early delivery. For business at these levels there are now plenty of sellers, but they all report demand light The market, however, is quiet but firm.

TIN

Over the signature of George Ormsby, chief in charge of tin, a statement has been mailed to the trade setting forth the status of the market up to May 23. This shows that the supply of the metal in the hands of consumers, jobbers, dealers, and smelters on May 1 was 22,000 tons, including tin in ores and concentrates. It also states that the monthly consumption to May 1 has been only 3113 tons per month The interesting revelation is the amount of allocated metal still on hand—of 10,169 tons originally apportioned to the United States, there was a balance on May 23 of 2199 tons The effect of the report is difficult to gauge today, as it only reached the trade on Monday morning. Thus far, however, it has produced discouragement. It is figured that were consumption to increase to 4000 tons per month, it would take at least five months to use up present supplies in sight. An active market is not looked for soon on the strength of this report. Buying for future shipment when restrictions are removed has fallen off, but some has been done around 51c., with Banca tin offered at a fraction over 50c. per pound. The falling off in interest is attributed to the decline in London prices recently. There are two interesting unconfirmed reports, one to the effect that restrictions have already been removed on future shipments from the Straits, and another that those on Eastern shipments will be removed first, on English shipments second, and on Canadian last. The London market has turned stronger again with spot Straits quoted yesterday at £242 10s. per ton.

ZINC

Prime Western for early delivery is quoted at 6.25c., St Louis, or 6.60c., New York, with demand light. This is nominal. For future delivery 6.30c., St. Louis, is asked for July and 6.35c. for August, at which levels some business has been done. As a whole there is no improvement. The market seems to be marking time, possibly awaiting developments in steel and other lines. There is a big void in galvanized sheets, and when building starts and steel begins to move a decidedly better spelter market is almost certain. In the meantime producers are sitting tight. The recent advance from the 6c., St. Louis, level is generally attributed now to fairly good export demand, largely from Japan.

For high-grade zinc about 6.62½ to 6.75c. is asked and obtained. The quoted price of sheet-zinc is $10 per 100 pounds.

ORES

Manganese: The best that can be done on Indian high-grade ore is about 68c. per unit, American seaboard. Some transactions are reported. South American ore is offered at about 60c. per unit, American seaboard.

Manganese-Iron Alloys: American producers of ferro are now quoting $125 delivered for 78 to 80% alloy, less $1.75 per unit under 78%. The former price was $150. No sales are recorded. Re-sale alloy has sold under $100 per ton in the last week. Spiegel, re-sale, has sold as low as $27 per ton, delivered; and one producer is offering alloy at $30, furnace. There has been a fair business in the last week.

Tungsten: There are reports to the effect that some business has been done, particularly in Bolivian ore at as high as $10.25 per unit. Prices are largely nominal for high-grade ore at $7 to $10 per unit in 60% concentrate. No testing of the ferro-tungsten market is reported. Prices for high-speed steel average about $1.60 per pound.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

NEW TYPE OF STOPING-DRILLS

Drill engineers and manufacturers have been well aware of the fact that one type of drill could not be applied efficiently to all conditions of drilling. The old two-man piston machine is now used in relatively few places. One-man piston-drills, water hammer-drills for driving, rotating hand-feed hammer-drills for sinking, and air-feed stoping-drills for upper holes, are some of the developments of the past 15 years.

In each department of drilling, too, specialization has been found necessary with increasing competition and with the adaptation of new drills to work previously done by other means with less efficiency. The first air-feed stoping-drills were practically all of one type, consisting of the drill-cylinder proper, mounted on a reverse air-feed cylinder, in which the feed cylinder remained stationary and the air pressure carried the drill up to its work, supported on a piston rod between the drill proper and the feed-cylinder. The cylinder was clamped in a trunnion on a column-arm, or on a bar. These machines were offered for hard, medium, and soft ground, and for all conditions in drilling upper holes.

The Sullivan Machinery Co. was the first to introduce in this country that type of pneumatic feed in which the feed cylinder is attached directly to the pneumatic hammer, the feed piston-rod acting against an abutment. This type of pneumatic feed held supremacy for many years, in fact, is considered as the standard for non-rotating machines at the present time. Modifications of this pattern made by the Sullivan company included hard-hitting stopers for solid ground, light-hitting stopers for soft ground, and feed-cylinders of different diameters to provide a lighter or stronger holding power against the rock.

All of the earlier types of stoping-drills were rotated by hand. Demands of the past few years from the field for a successful stoping-drill include the following variety: (1) Light weight and small size to permit easy handling in high stopes; (2) automatic rotation to relieve the drill-runner of the incessant labor of turning the drill-bit by hand, particularly in hot stopes; (3) satisfactory regulation of the strength of the feed; (4) a water-jet for laying the dust when drilling in sulphide ores, or other formations in which dust is injurious to the health of the miner; and (5) automatic lubrication.

These are general outstanding features to which must be added in the design of a successful stoper, the usual features of convenience in handling, cutting-speed, air power, economy, simplicity of construction, accessibility for repairs, staunchness, and ability to resist wear and hard service. The first four of these elements need not necessarily all be combined in the same machine, but represent varying conditions called for by different fields. The last-mentioned features are essential to success in any satisfactory stoping-drills.

During the past three or four years the drill designers of the Sullivan company have been studying conditions and developing new features with the object of making stoping-drills more nearly meet these varying factors of the field. That their efforts have met with success in the types recently introduced may be judged from encouraging reports received from operators. Two of these new standard Sullivan stopers are shown in the accompanying illustrations. No. 1 shows class DT-44 light-weight hand-rotation machine, and No. 2 class DT-42 stoper with automatic rotation and water attachment.

The flexibility of the interchangeable part system, a vital element in all Sullivan drill design, permits the following combination and arrangements to suit different conditions: (1) DT-44 light-weight stoper, hand rotation, direct feed, dry, solid steel; (2) DT-44 light-weight stoper, hand rotation, direct feed, with water attachment and hollow steel. (3) DT-44 light-weight stoper, hand rotation, with reverse feed, either dry or water type, for solid or hollow steel. (4) DT-42 rotating stoper with reverse feed and solid steel, dry; (5) DT-42 rotating stoper with reverse feed, hollow steel and water attachment; (6) DT-42 rotating stoper with direct feed and solid steel, dry; and (7) DT-42 rotating stoper with direct feed and water attachment, hollow steel.

It will be seen that it is possible to furnish a stoper for practically any conditions. The light-weight stoper is a small, short machine, much lighter than any other stoper on the market. Its net weight is 66 lb., and with the feed piston drawn in, it is only 48 in. long over all.

The DT-42 self-rotating stoper is available for hot stopes or other places in which the demand is for a labor-saving machine. This is the first time that a self-rotating stoping-drill of satisfactory design has been placed on the market. The difficulty with rotating stopers has been of two kinds: (1) To provide a compact positive means of rotation; and (2) to furnish some practical means of retarding the feed so that in starting a hole or in 'fitchery' ground the feed may be controlled positively and immediately. The difficulty with previously designed rotating stopers has been that in these two classes of work, the forward action of the feed, combined with the rotation of the steel, would throw the bit off the inclined surface of the rock, or into the seam or vug, so that a stuck steel or a crooked hole was almost sure to result, with equally sure results in loss of time and labor and frequent damage to the drill itself. In the Sullivan rotating stoper, the rotating mechanism is of the same type that has proved so successful in Sullivan DP-33 rotator hammer-drills and in the DR-6 mounted water hammer-drills. The parts comprising the rotation are all at the front end of the tool. There is no separate rifle-bar, and the piston is not weakened by a hole bored in the rear end to receive that part, as is necessary with rifle-bar rotation. Experience with these new stopers, as well as with the standard hammer-drills referred to has demonstrated that this form of rotation is substantial, positive, and reliable.

The builders state that in their experiments with independent rotating motors mounted at the front end of the machine, it was found that the increased weight at this point caused the machine to be very unwieldy, due to improper balance. While the present standard arrangement lengthens the machine, it permits a good balance to be maintained, enabling it to be handled a great deal easier than would be the case if the extreme front end were overweighted by a bulky mass of metal. The second element in the satisfactory rotating stoper, namely, control of the feed, has been the result of much study and experiment and is provided in these machines by means of a hand retarder or brake.

Among earlier unsuccessful developments were (1) pressure reducing-valves under hand control for varying the pressure of the air in the feed-cylinder. These failed, due to the unreliability of the valve, especially when wear took place, with resultant leakage; also to the fact that their control and operation is indefinite, as the operator has no means of knowing the extent to which the compressed air has been reduced in the feed-cylinder. (2) Feed-cylinders of various sizes were also experimented with, but these also were unpopular, due to the fact that a cylinder of any specified size is not sufficiently flexible to enable the operator to adopt the working pressure to varying ground conditions.

In the new Sullivan, the control is introduced by employing a reverse feed cylinder and piston, which is practically identical with the pneumatic feed mounting of the Sullivan 'pnufeed' rotator. A coil brake-band controlled by a handle is fitted at the front end of the feed-cylinder, the band surrounding or gripping the feed-piston in such a manner that the air pressure in the cylinder can be counteracted by a turn or two of the hand-grip, which is within easy reach of the operator. In spotting a hole with the bit held against the rock by the air pressure, the feed can be braked down to make practically an immovable mounting. When the drill has cut a satisfactory collar for the hole, the brake is released gradually, until full feeding strength is secured. The same method is employed for cutting through a seam, loose or broken ground, or a 'fitcher'. By tightening the brake, the rapidity of the feed is immediately reduced to the proper amount, so that the drill does not bury itself in soft ground, or drop out of line in crossing a vug or

Reverse Feed

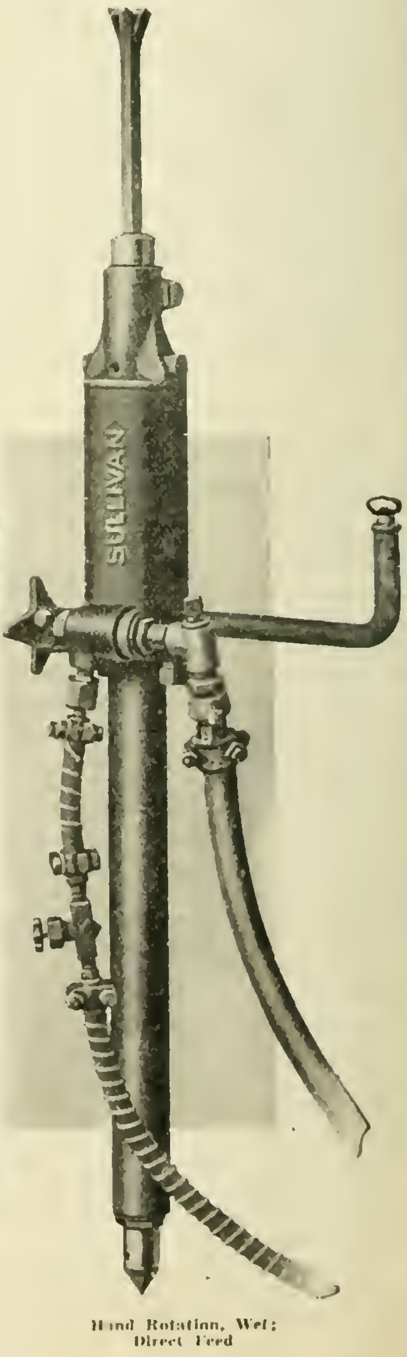
Hand Rotation, Dry;
Direct Feed



Hand Rotation, Wet;
Direct Feed

fitcher. This feature, as demonstrated in actual use in many parts of this country, gives complete adaptability for any ground conditions encountered from soft broken material to hard tough solid rock.

An important element in the success of the Sullivan rotating stoper with brake is the method of throttle control This is the standard Sullivan stoper throttle, which is used on all types. With the hose valve turned to its wide-open position, the control of the drill and feed-cylinder is placed under the one throttle. Turning the throttle first admits air to the air-tubes and oil-pockets, and in the next position to the feed-cylinder, raising the drill to its work Further turning of the valve causes the hammer to reciprocate slowly, and in the final open position, the machine is operated at full speed and the feed-cylinder receives full pressure.

Water-Stopers. The Sullivan drill designers feel that in the new water feature, which may be incorporated in either the DT-44 light-weight or the DT-42 rotating stoper, they have at last solved the problem of laying the dust and cuttings in a satisfactory manner. First attempts at this problem consisted in providing an outside water-spray by means of which water was drawn from a bucket through a hose on the injection principle and discharged by air pressure alongside the drill-steel, against the face of the rock. This method necessitated constant refilling of the bucket and kept the operator in a wet condition. In addition, it was quite unsatisfactory for drills rotated by hand, and was soon discarded. The next experiment consisted in a water-inlet at the front or nose of the drill, taking water from a pressure-tank or pipe-line. The water was then discharged through the hollow drill-steel, being assisted in this discharge by the air pressure, which found its way into the drill-steel from the front end of the cylinder.

There was considerable leakage, from the front end of the drill particularly, and the miner was apt to be fairly wet before the end of the shift. The object of the jet was accomplished, in that it discharged the water against the back of the hole while the drill cuttings were being formed, and laid the dust at that point. The constant leakage of water, however, proved a serious objection. A machine of this type was described by an unsympathetic drill-runner as resembling "a beautiful fountain playing in a park." On the other hand, it is customary for runners to operate the Sullivan water-stoper from one end of the shift to the other without becoming wet at all, except for an occasional splash from the sludge running from the drill-hole.

The form of water jet employed in the DT-42 stoper is that used with such success in the Sullivan DR-6 mounted water hammer-drill and in the water rotator. It consists of a water inlet to which a hose is attached from a pressure tank or supply-pipe, under control of the same throttle which admits air to the drill and feed-cylinder. Water is discharged through a central tube running well into the mouth of the drill-steel. This water-tube is surrounded by a jet of live air, taken from the back of the drill, which forms an effective seal against leakage at the chuck and also provides additional pressure to carry the water through the steel up against the back of the hole where it is needed. The action of the combined water and air throttle is to admit a small quantity of air to the tube or air-jet space first; as the throttle is turned to its next position, the water is introduced and brought to play in the drill-hole before the next turn of the throttle starts the piston moving with increasing rapidity. In stopping the machine, the process is reversed, so that the last thing before the air is finally shut-off a jet of live air blows through the steel, clearing out any water that may remain in it, and preventing this water from falling back into the chuck when the air is shut-off.

A detail of design that makes for the drill-runner's comfort, consists of a deflecting flange or cap, which forms a part of the drill-chuck This contains downward-looking ports for the drill exhaust, as is the case in all Sullivan stopers, so that dust or cuttings falling from the hole are not blown into the operator's face or against the upper part of his body. With the water-stoper, these ports act to carry off, without inconvenience to the runner, any sludge or water that may run down the steel from the hole and find its way into the front end of the machine

The great satisfaction reported by runners and mine superintendents alike, from many parts of the country, indicate that in this new machine a satisfactory self-rotating water stoper has at last been developed.

Automatic Lubrication. With each stroke of the piston a measured quantity of oil is drawn from a reservoir in the handle into the working parts of the drill. A supplementary oil-pocket in the throttle-valve casing is provided, which fills automatically with oil, when the machine is not in operation. On the opening of the throttle the entrapped oil is blown into the air-inlet passages of the cylinder, after which the automatic lubrication goes into effect. In the automatic rotation type the rotating mechanism is lubricated by an independent oiler in the throttle-valve, which blows oil into the ratchet chamber each time the drill starts working. In addition, the chuck-housing is furnished with a grease-chamber, from which the rotation parts are lubricated.

These new Sullivan stopers are both of the valveless pattern. The air-thrown piston is of the simplest possible design, and the cylinder is of one diameter throughout. In this design, the effort has been made to overcome previous detriments to valveless drills, consisting of high air consumption per unit of work done, and a rapid diminution of efficiency with increased wear. The Sullivan design embodies unusual simplicity in the number and shape of the working parts. The piston is equipped with ample bearing surface to insure it against wear and the design is such that when wear does occur, with inevitable increase in air consumption, the drilling speed will not be materially affected and the cushion which is provided at both ends of the piston travel is still retained in full effectiveness to protect the machine against undue jar and breakage.

As to drilling speed, results speak for themselves, reports from the field indicate that the machine measures fully up to the builder's expectations in this important particular The principal factors that determine drilling speed are force and frequency of blow. Wearing parts of these machines have been made simple and easy to replace. All parts are made on the standard Sullivan interchangeable system, and every part of the machine is made from drop-forged steel billets of special alloy metal or from tool-steel bars.

COMMERCIAL PARAGRAPHS

A. E. Hitchner has been appointed manager of the mining section of the industrial sales department of the Westinghouse Electric & Manufacturing Co. with headquarters at East Pittsburgh, Pennsylvania.

If mine and works operators wish to learn something about blowers, collectors, exhausters, and fans, they should procure a copy of Section No. 400 of the **Buffalo Forge Co.**, Buffalo, New York. Tables give capacities with speed and power requirements.

The **Hardinge Conical Mill Co.** reports the honorable discharge from war service of J. C. Farrant, its London manager. Mr. Farrant for over four years was held a prisoner of war in Germany. 1st Lieut. J. J. Cadot, of Air Service A. E. F., returns to take charge of the Denver office. Capt Harlowe Hardinge, Signal Corps, Director Radio Schools in the A. E. F., will return to his duties as vice-president of the H. C. M Co. in the New York office. The Hardinge Co anticipates the early return of three more of its staff and a consequent renewal of its pre-war service to its customers.

The spring number of 'The Yuba Bulletin' is an attractively prepared issue, showing the value of Yuba tractors in Californian agricultural operations. Besides pulling, a pulley attached to the tractor will drive stationary machines. Whether it goes through mud or is pulling stumps, the **Yuba Manufacturing Co.'s** Marysville, California, product does its work well.

The difference between the Allen sand cone and the slime cone is that the extent to which the spigot discharge is dewatered is under perfect control and is automatically maintained. The density of the discharge may be whatever is desired from the density of the feed to the density at which the dewatered product loses its fluidity. In No. 10 pamphlet, the **Allen Cone Co.** of El Paso, Texas, gives some interesting data on the use of its cone. To show how close is the regulation of density, samples taken every 15 minutes for 2½ hours only varied from 1.236 to 1.259, the average being 1.243.

Storage-battery driven locomotives, cranes, and cars are described and illustrated in Bulletin 1185 of the **Atlas Car & Mfg. Co.**, Cleveland, Ohio. These are especially suitable for about mines. The storage-battery loco has passed the experimental stage, and continuous service in some of our largest and most modern mines has proven its economy and reliability. A battery loco will replace from three to six mules and drivers with the same tonnage hauled, it is easily operated, and is practically fool proof. Exclusive features found only in Atlas equipment are the drive unit with its compact design, hardened and heat-treated steel gears and pinions, and accessibility for oiling inspection.

What they term to be "the greatest advance in oil-engine construction since the Diesel engine first came into practical service" is meeting with tremendous success in engineering circles in all parts of the world, according to R. R. Sweitzer, general manager for the **Western Machinery Co.** of Los Angeles, manufacturers of the Western heavy-duty oil-engine.

This engine, it is claimed, embodies all of the desirable features of oil-engines of the heavy-duty type, but does not have the intricate construction complications such as high-pressure fuel-pumps, high-pressure air-compressors, spray-nozzles, hot heads, hot balls, hot plates, or other means of surface or electrical ignition common to the Diesel or so-called semi-Diesel type. It burns fuel oil of low gravity, producing more power per pound of this fuel, is fully as efficient and economical in operation and because of its simplicity, highly-skilled engineering ability is not required in its maintenance and operating. The Western is built in sizes from 25 b.h.p. per working cylinder in multiples up to 6 cylinders. The dimensions of the 6-cylinder unit is 15 by 6 by 8½ feet.

The **Allied Machinery Co. of America** has increased its capital to $5,000,000. This was made necessary by the decision of the American International Corporation to group all of its machinery export-selling subsidiaries under one head. This move contemplates the complete absorption of the Allied Construction Machinery Corporation by the Allied Machinery Co. The Allied Machinery Co. de France and the Allied Machinery Company d'Italia will retain their corporate entities, but their parent corporation will be the Allied Machinery Co. of America rather than the American International Corporation as before. This is also true of the Horne Company, Ltd., of Japan, which was purchased early in the year by the American International Corporation. All shares of the Allied Machinery Company of America will, as before, be owned by the American International Corporation. The Allied Machinery Co. was formed in 1911 by interests associated with the National City Bank of New York to sell machine-tools in Europe. In 1916 it was taken over by the American International Corporation, which immediately set about to expand and organize the business on a large scale. The business has increased rapidly and today the company is operating in 14 countries. J. W. Hook will continue as president of the Allied Machinery Co., in general charge of the business. F. A. Monroe, S. T. Henry, and T. G. Nee have been elected vice-presidents. The first is in charge of the administrative affairs; the second is in charge of sales and advertising; while the last is in Japan devoting his attention to the affairs of the Horne Company. R. P. Redier is general sales manager, with headquarters at Paris.

Stockholders of the **Joseph Dixon Crucible Co.** held their annual and regular meetings on April 21. The following were elected: Directors—George T. Smith, William G. Bumsted, J. H. Schermerhorn, George E. Long, Edward L. Young, Harry Dailey, and R. E. Jennings. Officers—George T. Smith, president; George E. Long, vice-president; J. H. Schermerhorn, vice-president; Harry Dailey, secretary; William Koester, treasurer; and Albert Norris, assistant secretary-treasurer. Of the 20,000 shares, 19,512 were voted. The American Graphite Co., incorporated in New York, is a subsidiary of the Dixon company. Its directorate is the same, and officers practically the same, as those of the Dixon company.

The Dixon company announces the removal of its Philadelphia sales office from 1020 Arch street to rooms 801 and 802 of the Finance building, South Penn Square, in that city. This sales district comprises Pennsylvania, southern New Jersey, Delaware, Maryland, District of Columbia, Virginia, and West Virginia.

Threaded joints that are gas-tight, permanent, and easy to open can be made by using **Dixon's** graphite pipe-joint compound. This is made in paste form from selected flake graphite and a carrier. The experience of many years of producing this and the use by many of the largest railroads and gas companies have carried it to a high state of development. Because of the graphite used in its manufactore, threads can be screwed up a little more than with any other compound and the fineness of the graphite allows it to fill up the little cracks in the threads, giving a very tight joint. As graphite is inert to all known reagents, such as acids and alkalies, the metals are protected thoroughly from all kinds of corrosion. To burn graphite requires a temperature of 1400 to 1500°F. and pure oxygen, which makes the likelihood of burning out very small. The compound is smeared on the threads, and then screwed into the fitting, thus giving a uniform coating throughout. The use of this compound on long sections of pipe keeps up the gas pressure by preventing the troublesome leaks found along the lines. In addition, the ease with which the joints can be unscrewed makes it vastly superior to either red lead or white lead, which depend for their effect on the hardening of the cement. For use around the retort-doors where heavy asbestos gaskets are used, the compound gives the necessary lubrication so that the doors open easily without tearing the gaskets apart or injuring them. Here also it acts as a preventive of corrosive action and keeps the asbestos packing in fine condition for a much longer time than is otherwise the case. The advantage this compound has over red or white lead and other cements are the tight joints possible, the ease of opening, and the greater bulk. This compound for an equal weight has fully three times the volume, which means three times the number of fittings can be put together. Flanges, ground connections, cylinder heads—in fact, wherever metal surfaces come together tightly—can have 'pipe-joint compound' used to good advantage. This material is put up in small tubes, 1 to 25 lb. cans, and kegs of 50 and 100 pounds.

EDITORIAL

FRANCE has lifted the embargo on the importation of lead and spelter, as well as of copper. Other Allied governments, we hope, will do likewise soon, so that the normal trade in metals may be restored.

CLAIMS made for compensation by producers of chrome, manganese, tungsten, and pyrite under the War Minerals Relief Act number 1287 and represent a total sum of eighteen million dollars. The last day for entering a claim was June 4. No further applications will be received.

FRIEDRICH STAMPFER, the editor of the 'Vorwärts', exclaims: "It would therefore be lunacy to believe that peace would be brought about by putting six German names on one piece of paper." It would; but signatures are considered desirable as a matter of record; they constitute part of the formality of a peace conference.

HENRY FORD, or his secretary, says a good thing occasionally. He referred recently to the use of alcohol for generating power and stated that even now he was getting 10% more power out of an engine by using alcohol instead of gasolene. Whereupon he concluded by asserting that "it is safer for an engine to be full of alcohol than for an engineer to be in a similar position." Another example of the right thing in the wrong place.

AS yet we have not received the text of the U. S. Supreme Court in the Butte & Superior flotation case, but we can add to what we said last week that the Supreme Court reversed the decree of the Court of Appeals in so far as it held that the patent was infringed only when using one-half of 1% or less than one-half of 1% of oil per ton of ore, but sustained the Appellate Court's decree in holding that the use of "petroleum products and pine-oil in excess of 1% on the ore did not constitute infringement." The case is remanded to the District Court of Montana for further proceedings in conformity with this opinion, so that Judge Bourquin will have the last say, as he had the first also, six years ago in the Hyde case.

FROM Dawson comes the tragic tale of the death of twelve men out of 36 participating in a dinner on May 22 at the Yukon Gold Company's plant on Hunker creek. The cause is given as ptomaine poisoning. Four more are dangerously ill. Among those who succumbed are William C. Lawson, assistant superintendent, and John Grant, honorably known in Colorado. Ptomaine is an enemy against which the miner, especially in the North, has ever to be on guard, because the circumstances of his frontier life compel him to depend largely upon preserved foods. We venture to recommend to the mining engineer the habit of always carrying in his valise a small bottle of castor-oil as a medicine to be taken immediately a suspicion of ptomaine poisoning arises. Capsules containing castor-oil are perhaps more convenient to take on a journey. The prompt use of an emetic or a purgative is essential to mitigating the effects of the poison. We speak from a disagreeable personal experience.

CONDITIONS in Germany as compared with those existing in the countries that the German armies ravaged and looted are so pleasant that more than one observer has been moved to bitter remark. An Australian prelate, Bishop Frodsham, writes as follows: "In some strange fashion it is like awakening from a bad dream to go into Germany from the war-zone. To retrace one's steps and to pass, within a few miles, from the white well-ordered towns of Aachen and Herlusthal to the squalid actualities of Pepinster—to proceed, in a crescendo of desolation, to Liège, to Huy, to Namur, to Mons, to Arras, and to those never-to-be-forgotten plains of France, is horrible. The transition fills one afresh with fiery indignation. Is it right, is it just, that Germany should not now be made to feel the true horrors of war—war as waged by Germans? Compared with the injuries they have done to others, the Germans are suffering nothing, and because they are suffering nothing they are neither sorry for the past nor desirous to amend in the future. It may be impossible in practice to alter this state of affairs, but it will be unutterably base and unjust if Germany is allowed to profit by the injuries it has wantonly and deliberately done to the French industries by getting away with the goods." Put this in your pipe when you think the terms of peace are too severe.

ECONOMISTS, even the more conservative of those devoted to the dismal science, are beginning to discuss bimetallism seriously in the light of recent events, more particularly the removal of Federal restrictions on the exportation of silver coin or bullion and the British declaration of a government monopoly on shipments of gold out of the United Kingdom. Despite their dislike of a resort to the bimetallic standard, they recognize the possibility of a reversion to it, in consequence of the stress of new circumstances. Paper currency has so generally replaced coin, and credit has been expanded so dangerously, that the wise ones doubt whether there is enough gold in the world to supply the necessary 'cover'. Even now the exportation of silver is controlled by licenses issued by the Federal Reserve Board, and the British Treasury exercises similar supervision over the outward movement of gold. In Canada the suggestion is being made that even shipments of gold ore to foreign smelters shall be compensated by the return of a quantity of gold equal to that taken out of the country in ores. It is evident that the need for husbanding the precious metals, as the foundation of paper money, is being considered by those in authority. The old argument, valid as it was, against the double standard, namely, that the adoption of it would involve the disappearance of the gold, has lost much of its force now that all the belligerent countries are really doing their business on a paper, not a gold, basis. In these matters, as in others, Great Britain and the United States are co-operating. What was impossible 25 years ago may be practicable now, because the exigencies of war have brought the principal nations together in such a way as to facilitate unity of action.

A CIRCULAR issued by the Eureka-Croesus Mining Company has come into our hands. The conjunction of 'Eureka' and 'Croesus' is a little like painting the lily or gilding refined gold, but we presume that it is the natural consequence of juxtaposition, not of what might be termed fiscal exuberance. The circular tries, not unsuccessfully, to do justice to the name. It is a mine at Eureka, Nevada, a district made famous as much by a great lawsuit as by its production of lead and silver forty years ago. It is said, in the circular, that "in many places in the old workings are breasts of high-grade ore left in place when the mine was closed." This is unlikely, although we are well aware how ore in an abandoned mine, especially if under water, has a way, in local gossip, of becoming richer the longer it remains untouched. In the old stopes, it is said in the circular, are "very large quantities of ore, too low-grade to be profitably mined and treated at that time, but of sufficient value to make them very high-grade milling ores when treated by the economical processes now in general use." Average samples are stated to "show values of better than $25 per ton." This again is unlikely; indeed we have heard of "average samples" that ran so much less as to make this estimate look careless. The writer of the circular, whose name is not significant, says that, allowing $5 per ton as a treatment charge, which, he says, would be "largely in excess of the actual cost," there would be "$20,000,000 left from the million tons of visible ore." How visible? Visible to the unaided eye or to the eye of an exuberant imagination? $15,000,000 net profit is a tidy sum even in these days of billion dollar affairs. It is no wonder that the capitalization of the Eureka-Croesus Company is said to be "only" $1,500,000, and that "it affords the safest and most profitable mining investment now known." If these statements were verified by the elaborate sampling of competent engineers, it might come within the category of at least an eminently sane speculation, but the circular gives no proof of an examination such as would warrant such a positive appraisal of the resources left so considerately by the former owners of the mine. Major Catlin's name is mentioned several times, but we decline to believe that he is a party to this flamboyant prospectus. It is too lacking in essentials and too much burdened with trumpery. For instance, Clarence King is quoted, not verbatim, as having "expressed the firm conviction that below water and in the property of the Eureka-Croesus Mining Company would be found the greatest gold mine ever discovered." The context suggests that King said this to Major Catlin; we doubt it; as also we doubt the statement that it is "his (Major Catlin's) belief that the property will become richer and the ore quantities greater as additional depth is gained." That is an old nursery tale, a pretty fantasy, on a par with the tale of the treasure at the rainbow's end. Such talk is out of date, but it goes well with the next assertion in the circular: "When this property shall be [will have been] developed as a whole there will be nothing comparable to it as a precious metal producing property in the Western hemisphere, either in richness or magnitude throughout." We appreciate the self-restraint of the broker or promoter, or whatever the writer may be, for he might as well have included the Eastern hemisphere, balancing "Eastern and Western" hemispheres with "richness and magnitude". He drags the Homestake and the New York & Honduras Rosario into his story, as if the yield of ore in these two mines, in South Dakota and Central America, had anything to do with the case. His geographic amplitude does not stop there, he quotes the Alaska Treadwell, to prove that if $2.17 ore in that mine could be exploited profitably then the poorest ore in the Eureka-Croesus is a sure source of wealth: for, "in all the assays that Major Catlin has had made of the Eureka-Croesus ore, notwithstanding the fact that he diligently sought the leanest ores obtainable, he never has been able to get one running under $2 gold." Tell that to the horse-marines, my dear Sir. A miner does not "seek diligently for the leanest ore"; if he does, he needs the services of an alienist; and if, as a vagary, the Major sought lode-matter or veinstuff containing less than $2 in gold, he would have found it easily enough. There is lots of it at Eureka, even in a mine with $20,000,000 worth of phantom ore. The circular closes with a prediction that "the production of the company on a large scale will continue [but it has yet to begin!] without interruption for a long period, undoubtedly through several generations [most men outlive most mines, fortunately or unfortunately, as you look at it], and when the incontrovertible facts [he means 'cheerful expectations'] regarding the property become generally known among conservative investors [meaning venturesome simpletons], the stock will command a price warranted by the value [or otherwise] of the property," which (as amended) is true.

Copper in Arctic Canada

In this issue we publish an article on the deposits of native copper in Arctic Canada; it is written by Mr J. J. O'Neill, of the Geological Survey of Canada. Last week, in commenting upon the remarks of Dr Willet G Miller concerning the scope for prospecting offered by the vast area of pre-Cambrian rocks in northern Canada we dwelt upon the possibilities of mineral discovery in these outlying regions. We are glad therefore to print the information given by Mr. O'Neill concerning the distribution and mode of occurrence of native copper in the North, supplementing the suggestions of Dr. Miller concerning the resources of the north-eastern country between Hudson's Bay and the Labrador coast. Of all these far northern districts the Coppermine River is the one most conspicuous in the records of exploration. Mr. O'Neill summarizes the knowledge available concerning these deposits of native copper, the special interest of which lies in their analogy to the amygdaloid lodes of the Lake Superior region. Further information will be found in a paper by Mr. J. B. Tyrrell published in the Transactions of the Canadian Mining Institute in 1912. The copper deposits are near the mouth of the Coppermine river where it enters the Arctic Ocean at the head of Coronation Gulf, one of the most remote and least accessible places in the world. The existence of native copper on the banks of this river has been known for more than two centuries and its Indian name, Tzan dézé, meaning Metal river, shows that the natives were aware of the fact. They made use of the native copper in fashioning implements. The first white man to bring a description of these deposits was Richard Norton in 1717. It was the son of this Norton, who later became Governor of the Hudson's Bay Company, that sent Samuel Hearne to explore the Coppermine country in 1770. He knew nothing of mines or minerals, hence his report has no technical value. In 1822 Captain Franklin, afterward the celebrated Sir John Franklin, on his return from an Arctic voyage, made a survey of the lower part of the Coppermine river and recorded the finding of native copper in the valley-bottom, remarking that the Indians had ceased to search for copper as soon as they were able to buy ice-chisels and other instruments of iron at the trading-posts of the Hudson's Bay Company. In Franklin's party was Sir John Richardson, the naturalist, who described the native copper as being found in association with prehnite and calcite in an amygdaloid rock, and also in the reddish sandstone underneath. Richardson's account is most interesting. He says that the Indians obtained their copper from detritus in the valleys, not from lodes in place. In 1902 David Hanbury found native copper in basalt on Bathurst Inlet and Melville Sound, 175 miles east of the Coppermine river. In 1911 V. Stefansson reported rocks rich in native copper in the mountains north-east of Prince Albert Sound on Victoria island, in latitude 70 N. The late James Douglas, half in jest, undertook to grubstake his kinsman Mr George M. Douglas if he would examine and report upon "the copper-bearing rocks of Hearne's Coppermine river." He accepted the challenge, and organized a party consisting of Dr. August Sandberg, a Swedish geologist, Lionel D. Douglas, a lieutenant in the British navy, and himself. They started from Edmonton on May 11, 1911, and descended the Athabasca and Mackenzie rivers to Great Slave Lake, thence up the Bear river to Great Bear Lake, up the Dease river and the Dismal lakes, and then down the Kendall river to the Coppermine. They reached the object of their journey on August 17, and spent the winter in the Arctic, returning in October 1912. The story of this journey is told with great charm in a book entitled 'Lands Forlorn' written by Mr. George Douglas and published in 1914. Dr. Sandberg was able to examine only a small part of the region, but signs of copper were found over a distance of 300 miles. Dr. Douglas, in his preface to the book, suggests that "the total area within which copper ore may possibly be found covers nearly ten thousand square miles." The Douglas expedition confirmed Richardson's identification of the copper-bearing rocks with the amygdaloid melaphyres and conglomerates of the Keweenaw series of Lake Superior, as was proved by a petrological examination of many specimens brought from the Coppermine country and examined by Mr. L. C. Graton. Such samples as were brought home assayed from traces up to 7%. Dr. Douglas concluded that "the region may become one of the great copper producers of the world." He recognized its comparative inaccessibility, but he pointed to the fact that "the easternmost exposure of these rocks, so far as known, is not more than 500 miles distant from navigable water in Hudson's Bay, over a possible railroad route." Now a railroad is nearly completed to Port Nelson, on the western shore of Hudson's Bay. Lignite is plentiful, and better coal is likely to be found nearer than is at present known, judging from analogy with other parts of the North-West. It seems a far cry from San Francisco or New York to the Coppermine river or Bathurst Inlet, but some of us will remember when Frederick Schwatka's description of his voyage down the Yukon in 1883 first made known that great river to the outside world and how his fascinating articles in the 'Century' magazine were followed fifteen years later by the romantic story of the Klondike rush. As Mr. O'Neill says, it is doubtful whether the copper-bearing rocks of Bathurst Inlet are a continuation of those in the Coppermine district. The numerous islands of the Inlet show native copper disseminated in basic flows of lava, but assays show only up to 0.25%, whereas the amygdaloid portion of the lava-flows yield assays of several percentages; so there is an opportunity for intelligent prospecting in this region also. The area is enormous and it remains for the engineer to make systematic search for those parts of the copper-bearing formation in which the copper is concentrated sufficiently to make ore. These Arctic and sub-Arctic regions are distant and rough, the summer is short and the winter severe, but Alaska and the Yukon have proved that enterprising men can overcome the handicaps of nature and live more healthily in the North than in the hot jungle of the tropics. Those who are accustomed to the winters of Lake Superior will find nothing more rigorous on this continent. We see no real obstacle to further exploration and eventual exploitation except the difficulties of transport, now to be lessened greatly by the building of the railroad to Hudson's Bay; so here is a field well worthy of the combined energies of the capitalist and the mining engineer.

Big Issues and Small Minds

When the Armistice was signed last November the warring peoples gave a deep sigh of relief, and some even jubilated hilariously, because they thought the War was over and peace would follow forthwith. Seven months have gone, no treaty has been signed, warfare is in progress on seven fronts, and recrimination on seven more. The Allied nations find that victory has created difficulties and burdens chilling to the warmth of their elation, whereas Germany and her dupes have begun to realize the consequences of defeat and the penalties of crime. The world is disillusioned, disappointed, even resentful. Nowhere is this state of mind more apparent than at Washington. There the rejoicing in victory, the happiness at the prospect of ending the great horror, the pride in American achievement, and the solidarity of patriotic purpose have given place to the feelings much less exalted, even to some that are mean. The national representatives at the Peace Conference are ridiculed; the President is the butt of envy, hatred, and all uncharitableness; even the Allies, our brothers in arms, are mentioned in terms hardly more appreciative than those applied to the Enemy. It is a sad world, and Washington cuts the sorriest figure in it just at this time. At a crisis in our national affairs calling for calm judgment and wise decision, we see the violent effervescence of the most narrow-minded partisanship and the play of the most petty politics. Senator Johnson attacks the President noisily, he protests that this country is being forced into an alliance with bankrupt nations, into "a league of armed nations in a gigantic war trust," and will be forced to "guarantee the bondage of every suffering people." Three days later he comes out as a candidate for the Presidency. Senator Lodge suggests that the President is responsible for letting Wall Street financiers get hold of advance copies of the treaty, for nefarious purposes, as if the alternative explanation of leakage through foreign agents were not obvious; Senator Borah charges the President with "a treacherous scheme for the betrayal of the American people," and Senator Reed splutters his usual inanities. We are not in politics; we are not sympathetic toward Mr. Wilson as an individual; but we do respect the office of President and we have also some sense of fair play; therefore we think it high time to protest against the campaign of vilification to which President Wilson is being subjected. If representative government is to be effective, we must show some respect for our foremost representative, duly elected by the people of the United States. Pitiful indeed is this sequel to a great and successful national effort. Our young men, and many times more young men from other countries, have died to defeat the piratic offensive of the Hun, to validate the sanctity of contracts, and to re-establish international law. Have these politicians at Washington so little regard for the honored dead that they must intrude their miserable little jealousies and their pothouse machinations into the settlement of the great affair for which the national flag was carried forward so gallantly to victory? As for the rest of us, we also are not without blame. Have we not shirked our proper interest and responsibility in the settlement now being concluded at Paris? We were keen on the news of battles and we hurrahed at the signing of the Armistice, but have we not overlooked the fact that all the effort of our two years of belligerency, and the four years spent by our Allies in bloody contest with the Enemy, are being consummated in this Treaty and in the covenant of the League of Nations? Too many of us are too easily annoyed by the delay; we want to have done with it; we care little about the details, particularly about the fate of sundry small nations about which we are spaciously ignorant, if only we can resume business along the old channels, even with the Enemy countries. We sneer at the ineptitude of our delegates at Paris and make sarcastic remarks about the whole conversazione at Versailles, as if we could bring such matters to a cut and dried conclusion in one-half the time. Let us show a little more sense and a larger measure of generosity. President Wilson and his assistants, Mr. Lloyd George and the British representatives, M. Georges Clemenceau and his aides, Signor Orlando and the Italian delegates, all of them, have been working themselves to death in the desire to bring the War legally to an end by arranging terms as nearly acceptable as practicable and as nearly just as possible. If the settlement had been given to a committee of lawyers and publicists of our own selection, would they not have found it enormously difficult to envisage all the problems and to adjudicate all the controversies? How much more difficult, how almost beyond the capability of mortal men, must be the framing of a plan that will commend itself to the representatives of a number of countries, alien in race and in speech, each of whom enters the council-chamber with ancient prejudices, national jealousies, and even a personal bias toward the interests involved. We think it remarkable that the Conference should have done so well and we are willing to accept the settlement, not without demur, but at least with the desire to give it a fair trial, believing that if it be rejected there will remain no alternative but the chaos of international strife and the probability of another calamity such as the one that darkened the sun for four long years.

DISCUSSION

The Status of Gold

The Editor:

Sir—I have been ruminating for a few days over Mr. Robbins' article anent the status of gold and his criticism of Mr. Van Dyck's letter appearing in your issue of February 1.

He says, "Great Britain issued her gold sovereigns of a legal weight and fineness and then . . . she printed £100 on pieces of paper and issued these as running mates for the gold coins, . . . and did it successfully on a large scale." In issuing her coins "the value," he says, "was arrived at by taking the value of an ounce of gold as expressed in terms of monetary nomenclature on the day that Act came into effect." If the British government of the present day were to take the monetary nomenclature of tomorrow or the day after as a basis on which to fix the figures on the face of the sovereign, where then does he derive his warrant to justify doubling the figures as expressed in the monetary nomenclature of today?

Mr. Robbins appears to be obsessed by the idea that a government by legislative action can infuse more labor-energy value into labor-energy value already existing in the shape of gold. In other words he assumes an Act of Parliament can take the material expression of one man's physical and mental labor for one day and immediately re-create it into the expression of two days' labor of the same degree of productiveness. Now, giving a new slant to Shakespeare's words, a rose by any other name would smell no sweeter, neither would an ounce of gold by any other name contain more labor-energy.

Mr. Robbins complains that I do not make clear what I mean by intrinsic and social value. I am glad to explain that I accept, as he himself does, Mr. Hennen Jennings' figure of the function of gold—"a storage-battery of human energy; its value representing a certain amount of labor at the command of the possessor of gold." I did not mean to imply that its value in the arts and trades and its value as a money metal constituted two distinct attributes or characteristics.

Mr. Robbins points out the case of Argentina. Argentina finds it feasible to use gold metal in domestic exchange in exactly the same way as the United States finds it feasible to use copper metal in domestic exchange; that is, as a token or promise to pay. He speaks of the domestic value of gold in Argentina being double its international value, yet he would hardly err so far as to speak of the domestic value of copper in the United States as opposed to its international value by reading that value from the face of a copper cent piece. If Argentina should, in the course of possible commercial complications, be forced to engage in an exhausting war and suffer defeat, what then would become of the "value" which Mr. Robbins reads to us from the face of the gold coins of her realm? The moment of surrender to the opposing army would wipe out the fixed domestic standard and the gold coins would revert to the international standard value according to the weight of pure gold contained in each. This international standard value is not eternal and unchangeable, but is, however, the least variable of any commodity and the sum total of social labor necessary to wring gold from the stubborn earth, refine it, and place it in the channels of exchange is the determining factor in establishing its international standard value.

I cannot agree with him that the fundamental regard for gold seems to be atavistic. The human regard for gold is evolved from accumulated practical experience. Among the most primitive communities of humans, equally with the most highly civilized, it has been discovered that there exists a more or less latent conflict between the individual and the tribe or community. Modern civilization has accentuated this by revealing still other diversities of interest between the citizen and the nation, between nation and nation, and between the nation and the world. Gold being the commodity of least weight and bulk in relation to the amount of human toil and mental exertion embodied in it, the individual or the nation possessing it will cling to it with uncanny tenacity, being consciously or subconsciously aware that should the diversity of interest between him and his fellows, or between that nation and other nations, break at any time into open conflict the gold will always buy the needs of life, even from an enemy, if enough is offered.

Admitting, as Mr. Robbins contends, that gold has advanced 25% in the unrestricted markets of the world and therefore admitting it to be permissible to clip 20% off the sovereign and the dollar, the doing of this would not add one ounce of gold to the world's visible supply. The weight of metal to the labor consumed in its production would remain in the same ratio as before. Furthermore, the ratio existing between the labor expended in creating a given unit of any commodity and the labor expended in producing an ounce of gold would remain as before. What Mr. Robbins appears to be contending for is more value or purchasing power in gold rather than weight or visible supply. There is no obstacle, he says, in the way of ascribing value to gold coin. If a government or a league of governments can ascribe value to gold coin, it certainly would be illogical and a waste of energy for such governments in the same breath to pass any Act calculated to stimulate gold production, seeing that in Mr. Robbins' estimation they are already endowed with the power to ascribe value to gold already in existence by reducing the weights of coins—to ascribe value sufficient to cover existing deficiency. If he objects to this argument as a misinterpretation of the terms of his proposal, I must point out that he contends for a 20% cut in the weight of gold coins to cover the advanced cost of labor, and a further cut, presumably 25 or 30%, to narrow the gap which he says exists between gold and indebtedness. Now, if governments can at will raise the figures expressing value by reducing the weight of coins, it is evident these governments would have no incentive to ask for, or to assist in, any increase of production. Legislation could then arbitrarily ascribe the maximum of value to the minimum of weight, and Mr. Robbins does not state anywhere in his letter that there is any limit to the ascribing power possessed by governments.

He says, "if gold were demonetized, it would immediately rise in comparative value." It appears to me he is here confusing 'value' with 'price'. I will agree that the price would immediately rise, but I cannot agree that raising the figures on the faces of gold coins would give the possessor of gold more security in permanent value "at the present time," as he says, "when there is great unrest throughout the world." A parallel might be drawn from the fluctuation of prices of lots in a boom town. One might conceivably buy a lot at a temporarily high price and find himself the owner of a lot of future and permanently low value.

It is always safe to have the metal of the medium of exchange fixed at a comparatively low nominal figure in proportion to the cost of labor involved in its production. When the price of that metal becomes high in proportion to the cost of labor then it becomes dangerous as a medium of exchange owing to the fact that there is too wide a gap between its price and its value. Any political or social upheaval is likely then to bring financial distress. Of course, the fixing of a comparatively low nominal figure on coins is not a cure for all economic ills.

Mr. Robbins says that successfully and on a large scale Great Britain issued Consols and gold coins, and that both coin and Consols have no essential difference and are both money, and immediately points to the "grave financial situation"—caused by a paper currency he says. I would ask Mr. Robbins why did Great Britain ship those train-loads of gold to Canada to settle for war commodities purchased of the United States? If Consols are also money why did she not send this lighter money? Because Consols are but a promise to pay, while gold is payment itself.

The remedy for the "grave financial situation," which Mr. Robbins assures us exists, lies far remote from any altering in weight of gold coins or altering of the figures on their faces. A discussion of the application of such a remedy would be most interesting, but such a discussion would enter too far into the writhing intricacies of political economy and social relations to be immediately pertinent to the question of the status of gold.

Seattle, May 24. JOHN C. MCPHERSON.

The Flotation Issue

The Editor:

Sir—When I read some of your discourses on the evils and folly that enter into the affairs of the mining world I am thankful that there is an editor with brains and fearless enough to speak plainly and dispassionately regardless of consequences. When I read the court procedure in the Minerals Separation case, it seems as if immature minds were arguing, at the public expense, for their own enlightenment.

They did not invent anything; they simply experimented with, only, the elements that had been disclosed. Supposing a few weeks after the original patent was granted, over thirty years ago, some user of the process found that less than 1% of oil was preferable to a larger quantity, is it possible to conceive that our patent-office would give a patent that would be held valid, as a discovery and invention, when the inventor had opened gates into a field where not invention but intelligent use and experiment for economy and efficiency must arrive at or near the quantities to be used and the method of mixing, and prevent the original inventor from using the elements disclosed in the quantities and manner that would give the best results. Deferred action is immaterial; the submarine was left undeveloped over a hundred years!

It looks very suspicious that the M. S. company received a patent from Germany, whose patent system was to prevent anyone outside of Germany from getting protection; as the rejected claims in the offices of the patent attorneys in this country well show, they selfishly appropriated the brains of others after disclosure and rejection, possibly the kaiser or some of his satellites were interested in the future. All the brain atoms put into this world hold-up were put into scheming and now trying to befuddle the courts, for not a ray of brain-matter went into what they call an invention and discovery. There are souls so small that forty million can dance on the point of a needle. Files of patent applications, rejected, specially in German cases, should clearly disclose lack of invention by logical comparison.

Los Angeles, May 31. T. D. ROBINSON.

[Our correspondent is in error in speaking of the justices of the Supreme Court as "immature minds," although we quite appreciate how he feels about it. The various courts that have given such contradictory opinions did not lack intellectual force—quite the contrary, of course—but they were out of their element insofar as they had to deal with abstruse scientific principles and technical details outside their kin, and of this the litigants took advantage, with the result that the decisions are confusing and unconvincing to the detached onlooker.—EDITOR.]

FIG. 2. EXPOSURE OF COPPER-BEARING AMYGDALOID ROCKS ON AN ISLAND IN BATHURST INLET

Deposits of Native Copper in Arctic Canada

By J. J. O'NEILL

*INTRODUCTION. The Government of Canada decided in December last to withdraw from staking for minerals all of Arctic Canada lying north of 65° North latitude, and between 105° and 116° West longitude, "in order that the deposit of native copper reported to exist in that region may be thoroughly examined." See map, Fig. 1, accompanying these notes.

The objects of the present paper are threefold:

(*A*) To indicate the distribution and general occurrence of the deposits of copper referred to in the Order in Council.

(*B*) To outline the general character of such an examination, and the conditions to be met in carrying it out, such as (1) means of access to the deposits, (2) amount of time available for actual work, together with the time consumed in travel and enforced idleness, (3) climate and general working conditions.

(*C*) To discuss the advisability of the use of aeroplanes for carrying out the work, and to indicate the most suitable bases from which such a scheme would be feasible.

HISTORICAL NOTES. It has been known for more than 200 years that native copper is to be found near the north-central coast of Arctic Canada; Samuel Hearne was the first white man actually to visit the deposits when, in 1771, he reached the Coppermine river, in com-

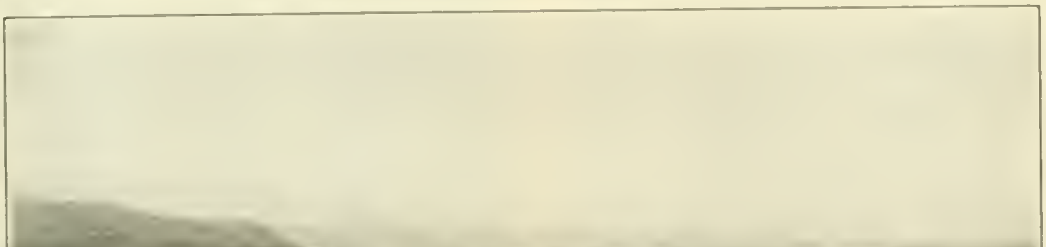


FIG. 5. TREE RIVER FALLS, SIX MILES FROM CORONATION GULF

pany with some Indians. His observations are of little value except as to the position of the deposit.

---

*Published by permission of the Geological Survey of Canada.

In 1821, Franklin reported that he found native copper along the Coppermine river, and also on the islands of Bathurst inlet; since that time Richardson, Rae, Dease, and Simpson, and Hanbury, have all confirmed both of Franklin's statements, but none of them had sufficient training to enable him to interpret correctly what he saw of these deposits. Most of these reports were exceedingly optimistic as to the amount and grade of copper ore to be found in those districts.

In 1835, Sir James Ross found trap-rocks on the east coast of Boothia in latitude 70° N. and notes copper ore from Agnew river.†

Large masses of native copper are found on the shores of Princess Royal islands, and large quantities of native copper on the shores of Prince of Wales island; according to DeRance‡ the copper at the first of these localities may have been carried there by the continental glaciers, but that on Prince of Wales island is not so easily accounted for, and may not be far from its source.

Copper in large masses is said to occur about 40 miles north-east of the head of Prince Albert sound, Victoria island; this was reported to Stefansson in 1910 by some Eskimos, and in 1915 many Eskimos testified to the Canadian Arctic Expedition concerning the same deposit; they produced some of the copper and said that masses much larger than a man protrude from the hillside, but whether they occur in solid rock or in drift could not be ascertained from them.

In 1917 a patrol of the Royal Northwest Mounted Police reported finding native copper in rocks about 60 miles east of Bathurst inlet, as shown on the map; the information from this locality is, like that from the others, very vague.

In summary, then, there are two large areas of copper-bearing rocks, namely, about the Coppermine river and in Bathurst inlet, which were first reported by Indians and Eskimos and later were visited and their occurrence confirmed by white men; two other areas of unknown extent have been reported by white men, one on Boothia peninsula, and one east of Bathurst inlet. Eskimos report that there are deposits of native copper in central Victoria island, on the Princess Royal islands, and on Prince of Wales island; the first and last of these reported occurrences seem worthy of some investigation.

Definite information has been obtained concerning the Coppermine river deposits by a party sent there in 1911 by the late James Douglas; the results of this investigation were presented at the annual meeting of the Canadian Mining Institute in 1913 in a paper by Dr. Douglas himself. The Bathurst inlet deposits were examined and mapped by me, in 1915 and 1916, while a member of the Canadian Arctic Expedition, and a summary of my results is printed in the bulletin of the Canadian Mining Institute for March 1917. Both these investigations were in the nature of reconnaissances, but a review of the data obtained will enable one to form some idea of the possibilities of the region.

THE COPPERMINE RIVER. These deposits are found in a series of superimposed flows of basaltic lava, with occasional interbedded conglomerates or sandstones, which occupy a belt 16 miles wide, and something more than 40 miles in length. This belt is known as the Copper mountains; it crosses the Coppermine river about 40 miles from the mouth, and runs in a direction a little north of west. The flows and sediments dip toward the north at about 12°, so that only the edges are exposed, the remainder passing under younger rocks to the north.

The Indians report finding copper in these mountains for 40 miles west of the Coppermine river, and Hearne's locality was about 25 miles east of the river; the deposits do not connect directly with those of Bathurst inlet, as was formerly thought, nor do they seem to swing out to the coast of Coronation gulf, so it is probable that they are entirely covered by younger formations somewhere within 75 miles east of the Coppermine, where they are cut off completely by the Laurentian granite.

The members of the Douglas party reported that they found native copper in place at Copper creek in an exposure of 30 ft. of basalt; the copper was in amygdules and as tiny shots or flakes in the massive portion of the rock. On Burnt creek they found copper similarly distributed through a total of 51 ft. of basalt, and in pebbles in 25 ft. of conglomerate. The assays ran from a trace up to one quarter of 1% of copper in the massive rock and up to 7.7% in the amygdaloidal portion. Copper stain was seen in many flows.

Just north of the Copper mountains the Eskimos find plates and masses of copper in large quantities in the drift.

Dr. Douglas considered that the information brought back by his party, although they only spent about one month in actual prospecting, was sufficient to warrant further extensive prospecting in that region.

BATHURST INLET. The copper-bearing rocks of Bathurst inlet are apparently distinct from those about the Coppermine river; they occupy an oval area which extends about 50 miles northwest-southeast and has a greatest width of about 25 miles. This area includes more than 150 islands ranging in size from a few hundred square yards to several square miles, also part of the western mainland, namely, Bank's peninsula, and a strip along the coast five or six miles broad extending from Arctic sound to Moore bay.

The formation is a series of basic lava-flows with a few thin beds of sediment; they are the youngest rocks in this region, and are exposed everywhere at the surface, since there is very little overburden of soil or drift. Prospecting would be an easy matter. The beds dip at about 6° (as shown in Fig. 2), so that they form a shallow basin, or basins in the area.

Native copper was seen on practically every island in this area as well as on the mainland. The distribution of the metal is remarkably uniform in the same flow

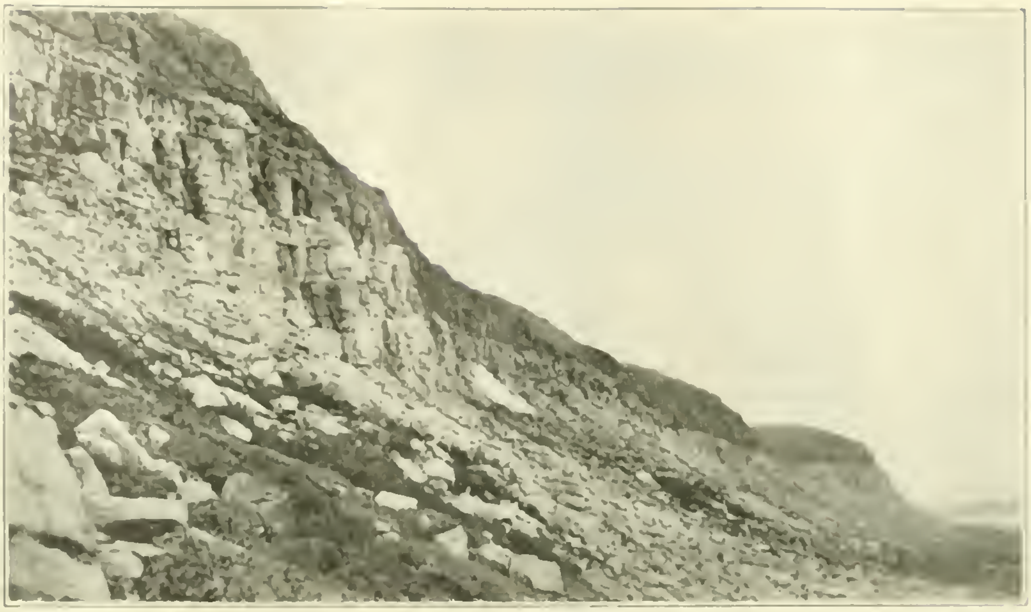

Fig. 3. THINLY BEDDED DOLOMITE CONTAINING BORNITE ON BATHURST INLET

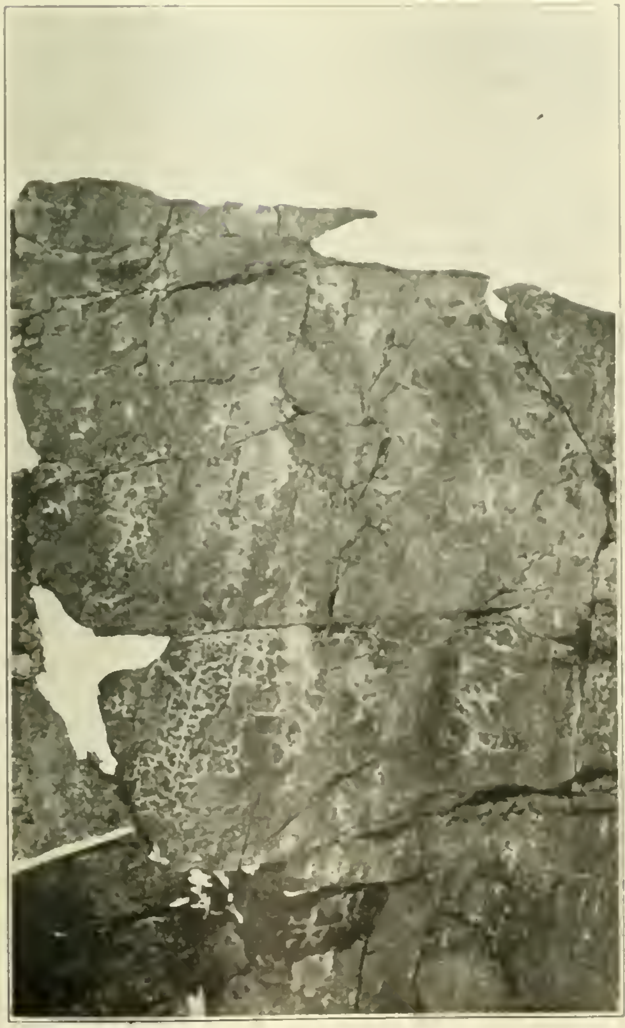

Fig. 4. SHATTER-PLANES STAINED WITH CARBONATE IN A SILL OF DIABASE CONTAINING DISSEMINATED CHALCOPYRITE. ON BATHURST INLET.

wherever found, for instance, one flow which was about 75 ft. thick, showed tiny shots or flakes of copper all through the groundmass; it was traced for more than two miles along Bank's peninsula and the copper content was apparently the same everywhere.

The native copper occurs in three forms:

1. As disseminated copper; minute flakes scattered throughout the dense groundmass of the basalts.

2. As amygdaloidal copper; irregular grains and small masses filling, or partly filling the branching gas-cavities near the surface of the basalts.

3. As vein-copper; in fissures and shatter-planes in any part of the basalts.

The disseminated copper may be said to be everywhere in this area, but the best to be expected from any of it is about 0.25%.

The amygdaloidal portion of the flows ranges from a few inches to several feet in thickness; in places this material will assay several percentages of copper, and in others the amygdules are entirely filled with chlorite, epidote, prehnite, opal, or agate. Where a flow is exposed at the surface this material is rather easily eroded, and the only broad surfaces now exposed are composed of the dense lower portions of the flows; the only place where the amygdaloidal portions may be seen is usually along the cliffs, and frequently there it is covered with talus. For these reasons it was not possible to judge of the relative extent and importance of this material during the reconnaissance mentioned.

The vein-copper assumes importance in some areas where the basalts have been considerably shattered, whether in cooling or otherwise, so that now they are traversed by a network of thin fissures containing plates of native copper, or vein-material containing native copper up to several percentages of the whole.

The problem to be faced in prospecting this area is to find the places where the amygdaloidal copper, or the vein-copper, or a combination of the two, is sufficiently concentrated to guarantee a large tonnage of profitable ore, and it may be possible to include considerable of the richer portions of the massive rock, to recover the relatively small content of copper.

I wish to emphasize the importance of investigating the deposits of sulphides in Bathurst inlet and to draw attention to the possibility that important deposits of sulphides may occur in the limestones of the Coppermine River region. In Bathurst inlet there is a series of dolomites immediately underlying the copper-bearing basalts, in the south and western portions of the region at least. See Fig. 3. This dolomite is exposed in several places in cliffs about the border of the area, and in three different deposits, a few miles apart, bornite was seen to have partly replaced the dolomite for several feet below the contact. Some of the thin layers were completely replaced, and others had masses of bornite scattered through them. The total amount of this material would probably have to be determined by drilling. An analysis of material from one layer six inches thick gave 49.87% copper.

Besides the bornite, which replaces the dolomites, there is a considerable amount of chalcopyrite disseminated through some of the large sills or dikes of diabase traversing the region. A grab-sample taken from one of these impregnations gave 1.18% of copper. See Fig. 4.

Accessibility. The deposits in Bathurst inlet are situated on tide-water and could be reached by ship around Alaska and eastward along the north coast through Coronation gulf; in the average season the ship should reach there some time in August, but it would probably have to winter there.

Under present conditions the deposits in the Coppermine River region can be reached best by way of the Mackenzie river and across Great Bear lake; they could be reached by this route by the middle of August, and the explorer would have to winter in the country.

Climate. The climate of the region under consideration is not extreme; in the winter the temperature seldom drops below −40°F., and seldom rises above 60°F. in the summer. The snowfall is about two feet; it is nearly all gone by the first part of June, and there is very little on the ground before the middle of October. The rivers open in the first part of June and do not freeze again until the end of September. Surface-work could be carried on from the middle of April until the middle of October without discomfort, and there should be little difficulty in carrying on underground work the year round.

Power and Fuel. Water-power in abundance for mining operations, and probably enough to take care of local transportation, is available from the Coppermine, Tree, and Hood rivers; the Coppermine river at Bloody Falls, is sometimes open all winter. See Fig. 5.

Coal, varying from lignite to bituminous, has been reported from the north shore of Bear lake, from the Horton river, from the north-east coast, and in central Banks island, and on the southern parts of the Parry islands.

Oil is known to occur in seepages in the Mackenzie valley as far north as Fort Norman, and the possibilities of production are being investigated by drilling.

There is plenty of spruce at the east end of Great Bear lake and in places between there and the Coppermine river; the tree-line is within 20 miles of the coast on the latter river.

Transportation. The main difficulty in prospecting or opening up the deposits of copper in Arctic Canada is apparently one of transportation; the problem is simply this: there are two large areas of copper-bearing rocks that are to be tested to determine if there is a sufficient tonnage of commercial ore to warrant the expenditure of the large capital required to place the district on a producing basis.

To carry out this testing by aid of the present means of transportation, the explorers would have to spend at least one winter in the country whether they went in by boat or overland by way of the Mackenzie river route. The party could be placed on the ground in August at the earliest and have about three months for work the same year before having to settle down for the winter; the next spring they could start in May and work until the middle of August before returning. Thus it is seen that in 18 months they could accomplish six and a half months' work. They could double this working-time by remaining another 12 months, that is, for 30 months they would accomplish about 13 months' work in actual testing. These figures are assuming the best organization, management, and knowledge of the country. By using aeroplanes a party could spend between five and six months each year in actual testing, and it would not be necessary to keep the men in the North during the winter; since the cost of labor is the largest item, it will be readily seen that the saving in wages, not to speak of provisions and outfit, would be an important factor in figuring out the relative economy of the two methods of transportation. For the investigation of the deposits of native copper in Arctic Canada by aeroplanes or hydro-aeroplanes, the most suitable base which is easily accessible to railway lines is on Great Slave lake.

Fort Reliance at the east end of the lake would be the best base for operations in the Bathurst Inlet region, and Fort Rae, on the northern arm of the lake, would be best suited as a base for an investigation of the Coppermine River region; from either place the route would pass along rivers and chains of lakes for the major portion of the distance, and by the use of hydro-aeroplanes, intermediate bases could be established as desired.

The total distance from Fort Reliance to Bathurst inlet is only 260 miles, and by using Aylmer lake and Beechey lake as intermediate bases this would be split up into three parts, each of 100 miles in length, and practically the whole distance would be over water.

The total distance from Fort Rae to Dismal lake, which is in the centre of the Coppermine River district, is 315 miles, and this can be split up as desired by form-

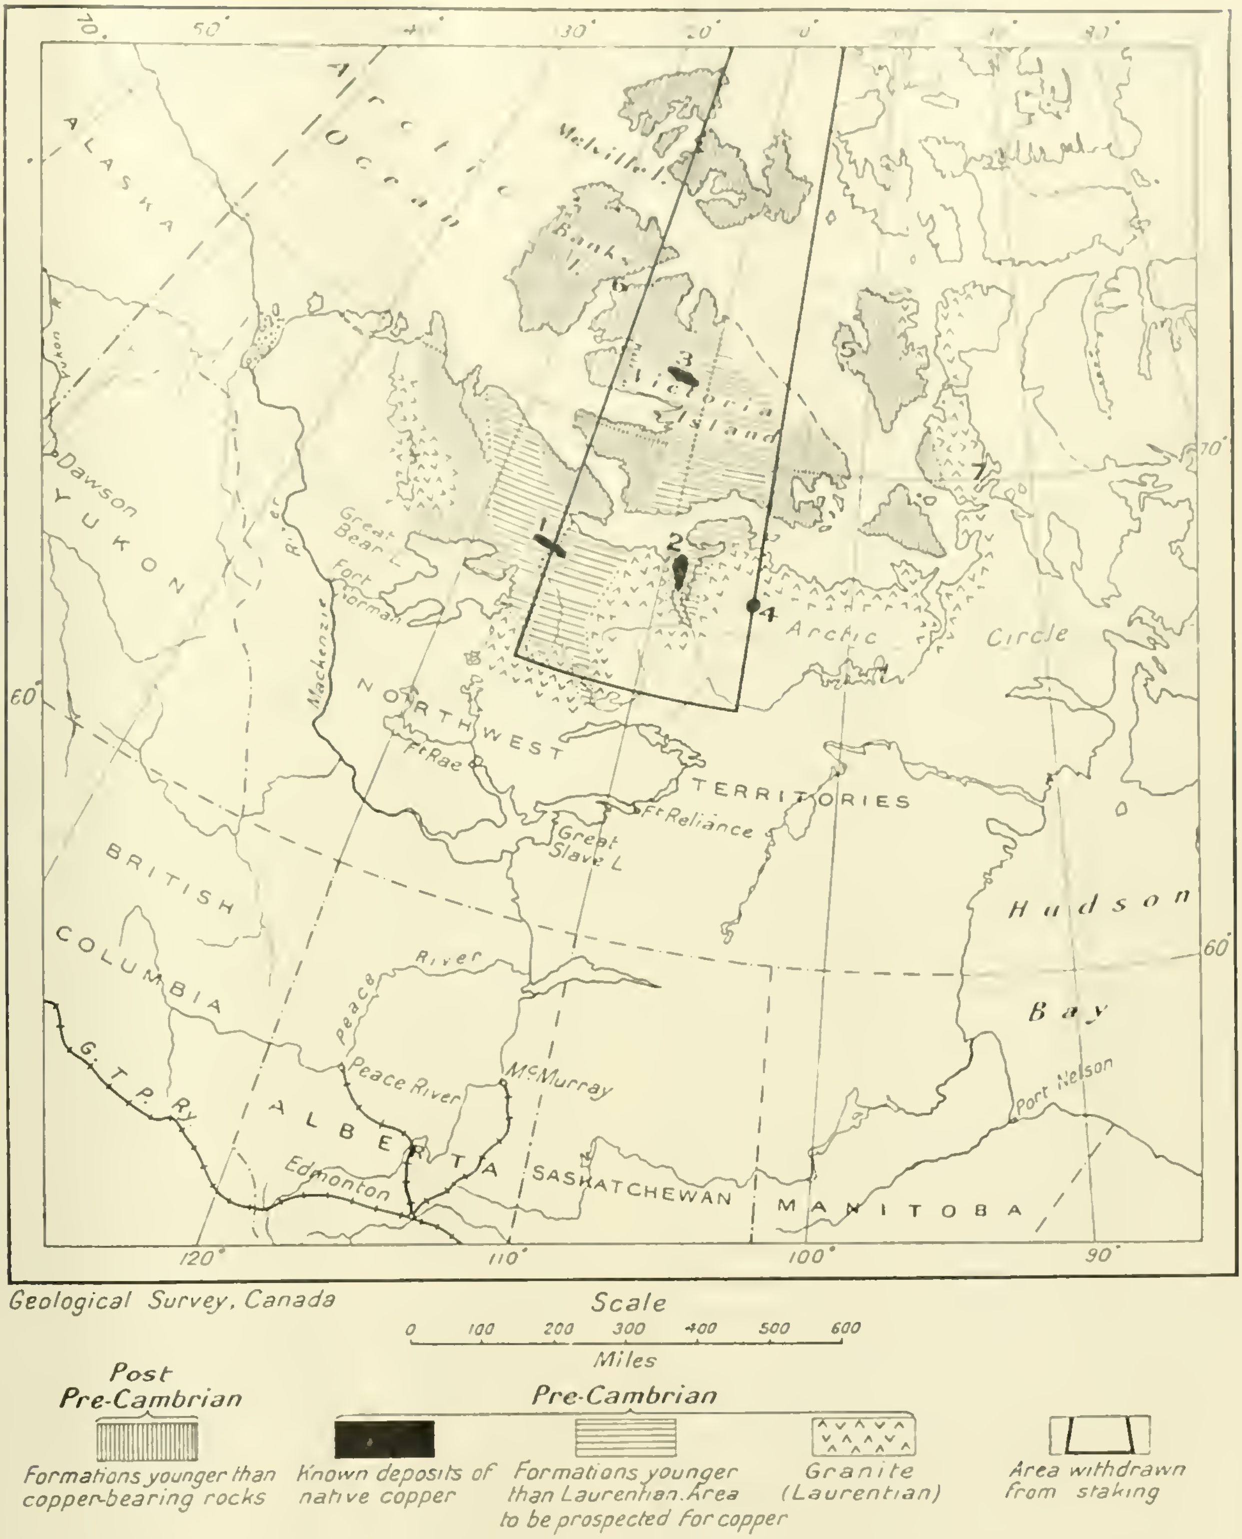

FIG. 1. MAP SHOWING THE GEOLOGY OF THE REGION ABOUT CORONATION GULF, IN ARCTIC CANADA, AND THE KNOWN COPPER-BEARING ROCKS

(1) Coppermine River area. (2) Bathurst Inlet area. (3) Victoria Island area. (4) Area reported by R. N. W. M. P. (5) Float copper on Prince of Wales island. (6) Float copper on Princess Royal Islands. (7) Boothia peninsula area, reported by Sir J. Ross.

ing intermediate bases wherever desired along the chain of large lakes along this route.

Thus it will be seen that by using an air-service, the trip can be accomplished in a few hours; under present means of travel it would require two months with the expenditure of a great amount of energy, and many chances of delay or even failure.

[The reader is referred to an article on 'Prospecting in Canada' in our issue of June 7, and to the interview with Dr. Willet G. Miller in the same issue.—EDITOR.]

A Metallurgical Journey to Shasta, California—II

By HERBERT LANG

Early Cyanidation. Almarin B. Paul's curious plant at the Calumet mine may be compared with the one erected to overcome the supposed eccentricities of the ore of the Tellurium mine on Middle creek. From a crusher the ore was fed to the hearth of a drying-furnace, 20 by 5 ft., under which the waste gases from a boiler were passed. The dried ore was then reduced to 30-mesh in a patent pulverizer, of a style now forgotten. It was then introduced into an agitator, where it was mixed with a solution, the composition of which has not been divulged, supposed to be competent to deal not only with the tellurium, which the ore may have contained, but with a large number even more deleterious substances, which it probably did not contain. After becoming sufficiently agitated, the mixture was passed to two rotating iron barrels, egg-shaped, measuring 3 by 4 ft. inside, and weighing 7000 lb. each, revolving on hollow trunnions like those of a tube-mill. With the pulp went 16 steel balls of 6 in. diameter. Rotation continued from 4 to 12 hours, according to the size of the particles of gold, the coarser ones requiring the longer time. Next came filtration; the filter, made of 10-oz. canvas reinforced by wire-gauze, was 4 ft. in diameter and took two tons of wet pulp. Pressure to the extent of 100 lb. per square inch was administered to the liquid, the filtrate going to a precipitating-tank 3 by 3 by 16 ft., lined with sheets of galvanized iron, in which the gold was abstracted from solution by plates of aluminum suspended in the tank. The gold, falling as a brown powder, was then gathered up and melted, while the residue from the filter was discharged over the dump. The saving claimed was 87%. Later it was ascertained that the 'secret' solution contained potassium cyanide, with some caustic soda. Herein we see an attempt at the cyanide process, a clumsy attempt, doing in a laborious and expensive way what by that time had been accomplished simply and in a rational manner. The dry crushing evidently was unnecessary, since the pulp was immediately wetted with the secret solution, and the double treatment, first in the agitator and next in the revolving vessels, could scarcely add to the efficiency of the process. Grinding in solution is indicated here for the first time, a practice that has been widely followed. The filtration under great pressure was a feature that further experience has shown to be unnecessary, but this fact was unknown at that time and for long afterward. Hence the excessive pressure employed was not so preposterous as would appear today. The extraction of 87% of the gold, if really achieved, was flattering, for it is not surpassed by current practice on ores of even moderate difficulty. If true, it proves that the ore of the Tellurium mine did not deserve its reputation for refractoriness; indeed, we may take it for granted that the ore was of no uncommon quality in any respect, and that no large proportion of the gold was combined with tellurium or with any other objectionable element.

It may seem to some that the treatment of the partly pulverized ore in a rotating barrel with the heavy steel balls foreshadowed modern practice with the ball or tube-mill; but one must go back farther to discover the germ of this inestimable invention. Some 15 years before the date of the Tellurium plant, Mr. Paul had built and was regularly using, at a mine in Butte county, California, a pulverizing appliance that was a close approach to the present forms of such mills. In connection with his noted dry amalgamation process, which he had installed in several mills, he used an apparatus described as follows:

"A revolving barrel, self-feeding and self-discharging, received the ore, already crushed coarsely under stamps, and revolved it together with pieces of quartz the size of the fist. The large fragments were used as a pulverizing material, the coarser pulverizing the finer, as well as being themselves worn down by attrition. The ore was thus brought to a fineness of 80 or 90 mesh. The internal arrangements of the barrel were such that the ore was passed through a series of sieves, only the first discharging outward into the hopper beneath, the remaining material returning to the centre of the barrel for further treatment."

This clearly antedates the modern style of pebble mill, which is often run with quartz masses instead of imported or other pebbles; and it is still doubtful which is the better. As for the use of balls within the rotating barrel, there is a bit of evidence still to be offered. The so-called Lundgren pulverizer, an apparatus in which cast-iron balls were employed as the comminuting agent, was used in the mills on the Mariposa Estate as early as 1864, as may be learned from the Government publication, 'Mineral Resources West of the Rocky Mountains'. This appliance consisted of a revolving barrel, 5 ft. long and of 3 ft. diameter, made of boiler-plate and lined with cast-iron plates one inch thick. It revolved 24 times per minute and required three horse-power to drive it. It worked dry, and took a charge of quartz weighing 800 lb., which had already been crushed under stamps to the size of wheat grains. With the quartz was introduced also 2400 lb. of iron balls, described as musket-balls, each weighing one ounce. In an hour, it was said, the ore was reduced to the finest flour; this was regarded as essential to the extraction of the gold by the subsequent amalgamation process, which, by the way, had a 'secret' about it, and was soon discarded. We note great divergencies between these methods, especially as to the weight of metal regarded as necessary for the pulverizing. In one case there was a very small number of very heavy balls; in the other a very large number of very light balls. The charges of ore weighed the same, namely, 800 lb.; whereas in the one case 2400 lb. of iron was used, amounting to three times the weight of ore, in the other only 512 lb. of steel was added, amounting to but five-eighths the weight of ore. In the one case there were but 16 balls, of the excessive weight of 32 lb. each; in the other there were no less than 38,400 balls (or pellets), or 2400 times as many. It is evident from this great divergence alone that no regular practice had developed, but that everything in connection with the comminution of ore was on an empirical basis. By going further into the 'dark backward and abysm of time' doubtless still more antique precursors of the tube, ball, or pebble mill might be discovered; but these instances may suffice.

CHLORINATION. When the chlorination process had become popular in California some 35 years ago, it was introduced into Shasta county, where the character of the ore and other circumstances seemed to favor it. The average run of the gold ores then being worked consisted of nearly pure quartz, intermixed with a small proportion, usually 2 or 3%, of sulphides, among which pyrite predominated; they were consequently precisely the material upon which that process had been found to work best. The ore itself was not, of course, subjected to chlorination, but only the concentrated sulphide—the essence of it, so to speak. The average run of such concentrate contained about 30% silica, the pyrite making up the remainder, with little gold, commonly not over 5 oz. per ton of concentrate. Nor is the process applied directly to the concentrate, which must be roasted so as to expel the sulphur to the utmost practicable extent before the chlorine can be made to combine with the gold and render it soluble. Whenever nature has thus expelled the sulphur, leaving oxidized iron compounds, the process can be applied directly, as was done at the great Mount Morgan mine in Australia, where the chlorination process was used on a big scale. Likewise an ore containing only quartz or some other gangue that is untouched by chlorine, and in which consequently the gold is in the native state, furnishes excellent material for the process provided the particles of gold are not too large; for chlorine attacks large fragments but slowly. However, although the process will work well on such a type of ore it is neither necessary nor advisable to use it, because amalgamation answers perfectly well on such material, and is much cheaper. Since chlorine is a powerful reagent, attacking many substances common to gold ores, its sphere of usefulness is contracted. In this respect chlorination is often compared with cyanidation, its successful rival. Chlorine is too strong; cyanogen is often too weak. The strength of chlorine is the weakness of the chlorination process; the weakness of cyanogen is the strength of that process.

Of the chlorination establishments built in California, numbering perhaps 50 in all, the average daily capacity was not more than two tons of concentrate. The average assay value of the material treated was about $100 per ton, in gold. Usually it carried a few ounces of silver, up to 10 oz., as at Nevada City. While the extraction of gold was usually complete, reaching 90% or even more, the silver was lost, being left in the residue. It was frequently proposed to extract the silver from the tailing by leaching with hyposulphite—the old Patera process—but this was rarely done, although it would appear perfectly feasible, because the average concentrate contained too little silver to warrant a supplementary treatment.

Copper, which interferes with the chlorination process, rendering the dead roast more difficult, and absorbing a certain amount of chlorine during the lixiviation, is generally absent in gold ores. The concentrate from the Mother Lode mines carries, as a rule, only traces of that metal and gives no trouble. Should it occur more abundantly, its separation is not a difficult matter, requiring a separate lixiviation with or without dilute acid, according to the condition of the copper, which may exist in the menstruum as sulphate or chloride, or in the residue as undecomposed sulphide or as oxide, the product of the roasting. Should salt be used, the copper becomes soluble as a chloride, which is then easily precipitated on metallic iron, or as sulphide by means of hydrogen sulphide or sodium sulphide. These reactions were well understood by Deetken, who introduced the chlorination process into California, by Kustel, by Riotte, and others, among the earlier practitioners, but they were never put into commercial use.

Neither the ores nor the practice differed much from those of other mining regions, and the series of operations may be summarized briefly. The original Plattner vat process was generally preferred, as against the so-called barrel, or Mears, method, the latter being characterized by agitation of the pulp within enclosed receptacles and under pressure. The advantages of the Mears method for large operations were acknowledged. The difference between the two processes extends to the production of chlorine, which is accomplished in the original invention by the reaction of sulphuric acid upon a mixture of common salt and the di-oxide of manganese; in the later process by the use of chloride of lime (bleach), which is mixed with the acidulated ore. Notwithstanding the greater labor involved it was urged that with material so rich as to repay very careful work, the vats, in which the pulp remained quiescent, were preferable. The lower cost of installation was another point. Charles Butters who brought the process to the highest pitch of efficiency in Shasta county, is ranked among those who advocated the vat method. This method, as carried out at the Golden Gate works, in Tuolumne county, was typical. The concentrate, derived from the auriferous quartz of that mine, amounted to 4% of the total weight of ore, and assayed from 6 to 20 oz. gold, with 2 to 4 oz. silver per ton. The tailing assayed from 0.5 to 0.85 oz. gold, and 3 to 5 oz. silver. Great, but unascertained, losses occurred, amounting perhaps to 15 or 20%, of the gold, besides the loss in the tailing. The concentrate, according to the invariable practice then, was roasted very slowly in a long-hearthed furnace rabbled by hand. This furnace was an excellent one in most respects, but it presented an example of bad construction because the arch was built too low, in obedience to the prevailing idea that the flame should be brought in contact with the charge, disregarding the principle of free-flame development. Three tons of material was in the furnace at one time, one ton being finished each day. A perfect roast cannot, of course, be expected, in the sense that all the sulphides are decomposed, and that all the sulphur is expelled, but the Golden Gate practice was good, regular tests showing but traces of soluble sulphates in the calcine. Three-quarters of a cord of pine wood was consumed to each ton of product, whence the fuel cost was $3.75 per ton. The total expense per ton was not far from $17, which was probably somewhat above the average of California chlorination plants. The reprehensible practice of adding salt to the charge, in imitation of the practice in silver mills, was followed, the addition being made when the woolly stage had been reached. At that time C. H. Aaron was just about to publish his observations on the volatilization of gold in salt roasting, the source of heavy and sometimes unexpected losses. These losses were no doubt heavy at the Golden Gate, but remissness in weighing and assaying had prevented their discovery. The late Professor Christy published the results of exhaustive experiments, which, had the process not been moribund would have had an important effect upon metallurgical practice. That it was possible, by long exposure to heat and the action of salt, to sublime and lose a fourth or even a half of the gold in a sample of pyritic material seemed incredible to even the most experienced operators; but so it was.

After withdrawing the roasted material from the furnace and allowing it to cool, it was then moistened slightly and placed carefully in a tank or vat made of wood, coated thickly inside and out with asphaltum paint, which is not attacked by chlorine gas. The calcine consisted approximately of one-third quartz grains, with two-thirds oxide of iron, partly ferric and partly magnetic. There were, of course, minor constituents, which, aside from the precious metals, need not be mentioned. The ore from which this material was derived was exceptionally simple in composition, showing upon analysis, scarcely any of the elements that we are wont to find in such a connection. There was, for example, no lead, no bismuth, no antimony, and but a trifle of arsenic. None of these play any part in chlorination provided the roast has been conducted properly.

It is necessary in the vat process to prepare the material so as to admit of the passage of the gaseous chlorine, through the charge, reaching all parts of it. It must be porous, in fact, but it cannot be wet. A little water is requisite, because the gold chloride must be dissolved as fast as formed, else the inside of the metallic particle will remain coated with the solid chloride and its decomposition prevented. Much water, by preventing the access of chlorine, spoils the operation in the vat, but does no harm in the barrel modification. It was generally supposed that chlorine was unable to attack gold in the absence of moisture; but this is a mistake. It attacks it dry and forms a chloride that is deliquescent, and the function of the moisture intentionally introduced is to dissolve immediately the newly formed auric chloride and get it in condition to be leached. The calcine is mixed at first with just enough water to enable the mass to hold together when squeezed in the hand. The moistened stuff is then shoveled, or, better, screened into the vat in a most careful way, avoiding a tendency to pack down, leaving it so that the gas can penetrate to all parts of the charge, which is about a foot and a half deep, and rests upon a canvas filter, which rests in turn upon a permeable layer of sand or gravel in the bottom of the vat. The operation goes on in the cold, and cold water is used to dissolve the new compound of gold and chlorine. It was regarded as a singular fact that a little of the gold in the Golden Gate calcine was soluble in water before the addition of chlorine; but this effect of undecomposed salt on metallic gold and silver is normal.

The precipitation of the gold from the very dilute solution resulting from leaching with repeated additions of water is easy up to a point, but to get all of it is another matter. A little remains persistently in the exhaust liquor, giving rise to not unimportant losses. The spent liquors were usually tested by the addition of ferrous sulphate and watching the color; but it is only by evaporating down an aliquot part and assaying the residue that an adequate idea can be obtained as to the extent of the loss. Many precipitants are known, but the general practice centred upon the use of copperas (ferrous sulphate) in preference to hydrogen, sodium sulphide, or charcoal. Most operators manufactured their copperas by acting on scrap-iron with sulphuric acid; for larger quantities, it would often be cheaper to make it from native pyrite by heap-roasting, after the manner in which the Mexicans make their magistral for use in the patio process.

Notwithstanding the certainty with which the reactions of the chlorination process take place and the simplicity of the operations and the apparatus, and the fact that 90% of the gold contents was habitually accounted for, it must be acknowledged that chlorination was a wasteful process. It can scarcely be doubted that millions of dollars have been lost in working the rich concentrate of the Californian mills, to prove which it is only necessary to consider the aggregate of the wealth contained in the tailing of the numerous chlorination plants scattered throughout the gold-mining regions. At one time there was over 40,000 tons of such tailing still preserved on the dumps of Amador county, which has always been regarded as the chosen home of chlorination, and where the art was carried on with unquestioned skill and intelligence. All this has been sold to smelters situated at great distances and treated at a profit. The Amador tailings averaged fully $10 per ton, a sum sufficient to pay both the cost of transport and the treatment charge, and yet leave a profit. Still larger quantities have been allowed to escape into the streams, to become a total loss.

A marked advance in metallurgy had been made early in the 'eighties by the introduction of the Plattner process of chlorination, which became popular throughout the quartz-mining regions of California, where, for many years, it fulfilled an important function. Previously the common practice in treating the gold-bearing pyrite, whether ore or concentrate, had been to grind in pans with quicksilver, trusting to fine comminution to render the gold amalgamable, or, in some cases, to subject it to a previous roasting. By this means a portion, only, of the gold was recovered, the remainder being allowed to run to waste with the tailing. This method was so wasteful that it was a question whether it paid to save the pyrite at all; accordingly, we find that in those years very few of the mills were provided with what would now be called an efficient concentrating plant. Progress was in the air, but nothing was more common than to find mills totally devoid of concentrators, while a small number had installed such makeshift contrivances as buddles and canvas plants, while the more progressive were just beginning to realize the effectiveness of the Frue belt-machine, which in time became the standard concentrator of the world. A great number of gold mills were provided with pans of the style common to silver-milling, and scarcely any other means was known of extracting the gold in the sulphides. Happily, through the skill and foresight of Deetken the chlorination process was brought over from Germany, and adapted to Western conditions. Wooden vats of considerable capacity took the place of the earthen jugs, and a suitable gas-generator was provided, capable of gassing a charge of a ton within two or three hours, which was considered a marvelous advance. It is rather curious that the process has remained substantially as Deetken left it 40 years ago; for the improvements suggested by later operators have never superseded former practice where close work is an object, although the capacity of the plants has been expanded.

In Shasta the ores adapted to chlorination were fairly abundant, consisting of the sulphides contained in the quartz treated in about 20 mills, aggregating 290 stamps. The stamps averaged about 850 lb. in weight. The largest mill was that of the Uncle Sam mine, west of Kennett, which had 35 stamps, and in 1896 had 14 Frue vanners, or two to each battery of five stamps. Previously, under the management of Daking & Co., it had 20 stamps with 4 Frue vanners and a canvas followed by a smell chlorination works, probably the first erected in northern California. Eventually the 4-ft. vein was followed to a depth of 450 ft., which in those days seemed a great depth, and produced in all as much as a million dollars. It is worthy of remark that while the Uncle Sam had 14 vanners with its 35 stamps, all the other mills in the county, with 255 stamps, had only 19 concentrating machines between them, or one to every 13 stamps. The Murray mine on Flat creek, not far from the Uncle Sam, had a cannon-ball mill and two concentrators. It worked a 2-ft. vein, the assay value of which is not recorded, but the 'sulphurets' were claimed to go $200 per ton. The Central mine, a more important property, on the east side of the Sacramento, used two Huntington mills, supplemented by 8 Frue vanners, producing, as the owners claimed, also a $200 concentrate. In the Old Diggings district, just north of Redding, there were the Utah & California, owned by the Walker Brothers, noted mine-operators of Salt Lake, and the Texas & Georgia, owned in part by R. G. Hart, another well known and much-respected operator, now deceased. Both mills had concentrating apparatus, and became customers of the custom chlorination works established at Kennett in 1889.

As the superior advantages of smelting for such ore had not become fully appreciated, and as the enormous base-metal resources of the region were scarcely suspected, it might have been supposed that chlorination represented the final word in scientific metallurgy. This, no doubt, was the general impression, otherwise shrewd operators would scarcely have thought of establishing, either in Shasta or elsewhere, a plant designed to do business on a custom basis. The limitations of the process were fairly well understood, and this process, so scientific in its principles and so simple in its application, proved no better adapted to the ores of Shasta than of any other region. As before mentioned, chlorination is only perfectly applicable to material that, like the calcined concentrate of pyritiferous gold-quartz, contains only the oxide of iron mingled with a little quartz left by the imperfect dressing. Any substance upon which chlorine acts is invariably prejudicial to metallurgical success, and a great deal of the skill and ingenuity of its devotees have been mainly expended upon devices for overcoming the harmful effects of such impurities. The inability of the process to deal with silver is well known; when this metal is present a secondary process is necessary. These peculiarities detract from the value of chlorination, which is not a method of general utility. Nevertheless it has been used as a custom process to a considerable extent, especially in connection with the ores of Cripple Creek and the Black Hills, where, for a time, it was regarded as equal in value to cyanidation. It has long since been superseded, either by cyanidation or by smelting. Even the concentrate of the Mother Lode mines is no longer treated with chlorine; instead this product is shipped, unroasted, to the custom smelters, or, in one or two instances, it is cyanided, raw, with better results. Mount Morgan, in Australia, affords the best instance of direct chlorination. The gold ore of that mine contains its iron as ferric oxide, a substance, as before indicated, wholly unaffected by chlorine and consequently not wasteful of that reagent. The prodigious quantity of such ore at Mount Morgan and the scale on which the operations were carried out, made it the most remarkable of all such installations; but even at Mount Morgan the process has long since been superseded by smelting, largely owing to the discovery of copper-sulphide ore underneath the big gossan forming the crest of the mountain.

While the numerous chlorination plants of California almost without exception were technically successful, only two or three of those devoted to custom work seem to have proved financially profitable. Nor is it to be expected that any great profit can be won in operating on the small scale made necessary by the scarcity of suitable ores. There were, however, a few noteworthy exceptions. Probably the plants of Voorheis & Barney at Sutter Creek and Drytown, in Amador county, were the most successful, they having, in the course of some years, carried on a regular business in the purchase and treatment of the concentrates of the neighboring mines of the Mother Lode, during which some 25,000 tons of dressed material was put through the two plants, with an aggregate output of about $2,000,000, and aggregate gross earnings of one-fifth that amount. The regular charge for treating concentrate was $20 per ton. In this case, as in others, the smelters and railways conspired to take away the ore upon which the local establishments depended, bringing operations gradually to a close. It was not found practicable to do the close work required upon the material of such value for much less than $20 per ton, although private plants, that is, those operated on behalf of a single mine, published statements showing a cost as low in one case at least as $6 per ton.

The ordinary extraction by chlorination was about 90%. We may believe that in most cases it was less rather than more, because the residue of tailing generally showed a value of about $10 per ton when the concentrate itself carried $100 per ton. It should be noted, however, that the tailing weighs considerably less than the unroasted material. Pure iron pyrite, perfectly roasted, forms ferric oxide, which weighs only two-thirds as much. The roasting, however, produces some magnetic oxide of iron, which weighs still less; but some silica and other stony impurities are always left in concentrating, often amounting to one-third of the weight. On the whole, therefore, the tailing may weigh three-fourths as much as the original material, whence the loss might be 7.5%. But there are other losses, the amount of which it is impossible to tell with accuracy, largely because the chlorination operators with few exceptions (among whom we must number Messrs. Voorheis & Barney) were not careful in matters of weight and assays. The principal loss, no doubt, arose from the volatilization of gold, a matter not fully understood or appreciated.

The ordinary practice of chlorination as conducted in California is well illustrated by the operations at the Golden Gate plant, in Tuolumne county. The method here used was the original Plattner process as improved by Deetken, who used wooden vats for the reception of the roasted material. This plant, at which I studied the process some 40 years since, dealt only with the product of a single mine, the concentrate being, with the exception of the inevitable quartz grains and a trifle of arsenic, composed of pure pyrite and therefore presenting no obstacle to successful work. The chief difficulty was an inadequate supply, the output of concentrate amounting to only one ton per day. This, however, was uncommonly rich, containing from $150 to $400 per ton in gold. The concentrate was first dried upon the top of the furnace, which was of the type called by the Germans a fortschauffelungsofen, a hand-worked reverberatory about 50 ft. long by 10 ft. wide, with the usual arrangement of doors, fireplace, and chimney. The hearth was made of soapstone, quarried near-by, and well adapted to the purpose, since it was sufficiently refractory to withstand the moderate temperatures required, and particularly because the smoothness of the bed materially lightened the work of rabbling. The roasting, and indeed all the work of this plant, was carefully done, great pains being taken to ensure a perfect roast, perfect gassing, and perfect precipitation. Doubtless the work at this little plant might be compared in these respects with that done at the most noted German plants, which it resembled in the minute scale of its operations. A dead roast being the aim, the charge remained in the furnace, under constant rabbling, for 24 hours, the heat never being suffered to exceed a dull redness, except toward the end, when it was raised somewhat to ensure the complete decomposition of any remaining sulphates. Three charges, of about 1500 lb. each, covered the three divisions of the hearth, and were kept separate. At a certain stage, namely, the period of maximum formation of sulphate, common salt to the extent of 5% of the charge was added, an indiscreet and probably useless proceeding, but practised by nearly all chlorination managers. This practice, copied from silver metallurgy, is without justification, since the effect of salt is to decompose sulphates but not sulphides. There may be a glimmering of sense in it, though, since the persistence of ferrous sulphate in the chlorinating vats would induce the untimely precipitation of the gold. But to secure decomposition of any small residuum of ferrous sulphate would only require the addition of a mere trifle of salt, quite at the end of the roasting, before the charge was drawn from the furnace, or even after it had fallen into the 'cub' but still remained red-hot. A better expedient would be to add burnt lime or lime-water subsequently, by which the sulphate would be effectually broken up, without the possibility of causing a loss of gold. Further, the reaction between salt and ferrous sulphate gives rise to ferrous chloride and sodium sulphate, the former of which volatilizes at a moderate heat, with results that later experience has shown to be almost fatal to the process.

It was at this period that Charles H. Aaron published the results of his observations on the volatility of gold when roasted with salt, thereby rendering a great service to scientific metallurgy, but weakening public faith in the chlorination process itself. He showed the possibility, even the probability, of great losses on this account, and denounced in strong terms the practice of salt-roasting. His statements were received with incredulity, but they have been verified in full by various experimenters, among whom S. B. Christy was the most prominent. It may seem almost incredible that years had to elapse before the fact was discovered, and we can only lay it to the lack of systematic weighing and assaying by the operators, who were content for the most part to jog along in the old way, until the smelting fraternity entered the field and took away their business. The practice of weighing and assaying the charges never became general at chlorination plants, though some, as at Sutter Creek, adopted it, and consequently the operators never knew quite what they were doing. In this respect the practice of the Golden Gate mill was as bad as any, and the plant ran on for years without a suspicion that heavy losses were being incurred.

The procedure at the Golden Gate works was identical with that followed elsewhere, and we may safely assume that the losses there were not excessively greater. What these were never was known: but it is significant of the looseness with which accounts were kept that the manager remarked at the close of a long campaign that while he got $70,000, it cost $80,000 to get it, and that he didn't know where all the gold had gone. It was directly after that that Mr. Aaron made his announcement of the heavy volatilization of gold from the Murchie concentrate; this gave a pretty good idea where the gold had gone, and set the chlorination operators to thinking deeply. Christy published his quantitative determinations somewhat later, and the matter was settled once for all.

THE BUTTERS CHLORINATION PLANT IN 1890

It will appear from the foregoing that the chlorination method is hardly applicable to large-scale work, although the proponents of the barrel system held to the contrary. We are the more convinced of the narrowness of its scope when it is considered in its relation to custom reduction of ores, as practised in a few plants. One of the most prominent of these was the establishment of Charles Butters, styled the Butters Ore Milling Works, at Kennett, in Shasta county. This was built in 1889, in a locality that then became and has since remained an important metallurgical centre. The Butters plant signalized itself by treating a variety of ores and products whose reduction by this method had not previously been attempted. Many of the expedients by which the difficulties of chlorinating complex or unsuitable ores were overcome are worthy of more extended description than space permits. Mr. Butters himself was surprised at the number and complexity of the operations that were sometimes required to be performed on a single vat of the chlorination plant. Here let it be said that he invented some ingenious operations, and mentioned them in a letter printed by him some 30 years ago, before his connection with the cyanidation process, which brought him fortune and reputation. Some extracts from the letter will throw light upon the expedients necessary in treating custom ores when competing with smelters, for at that time smelting had already become a powerful competitor. Mr. Butters brought auriferous material from points 200 miles away, "and came out," to use his own words, "more than even." The concentrate from the Idaho mine at Grass Valley gave much trouble; it contained lime and magnesia, together with manganese, zinc-blende, galena, and chalcopyrite, and assayed 4 oz. in gold, with 8 to 12 oz. of silver per ton. This material could not be roasted with salt, said Mr. Butters, "since the gold would go up the chimney.'' So it had to be roasted at a black heat, discharged, allowed to cool, wetted down, and screened rapidly, a little at a time, otherwise the pulp, being a natural cement, would consolidate. After the sulphates had absorbed all their water of crystallization, taking about two days, it had again to be screened carefully, put into a vat, and washed two or three days with cold water, then the carbonates and alkaline bases were neutralized with sulphuric acid, this taking from 60 to 100 lb. of 66° B. acid per ton. When the pulp had been acidified, 20 lb. of acid was added and circulated for 24 hours in order to dissolve the copper oxide. It was then washed for 48 hours with cold water, shoveled from the vat, the pulp was partly dried, screened, and transferred to a vat, where the chlorine gas was introduced. Mr. Butters said: ''When you have washed it out, precipitated, and got your clean spongy gold in elegant condition, you feel repaid for your trouble. The tailing, however, still contains from $4 to $6 per ton in gold and all the silver; and 'hypo' won't touch it, it having been roasted raw; and the acid does not dissolve out more than one ounce of silver to the ton. Now this has to be treated as a distinct ore; 5% salt is added to the wet pulp and it is put through the roaster just as fast as possible, when we get nearly all the balance. Gold is here united with the silver, and volatilization does not take place.''

Mr. Butters showed the inefficiency of ferrous sulphate as a precipitant, and in careful experiments found a temporary loss of 10% of the gold when the exhaust solution contained copper salts (chloride and sulphate). With less copper in the solution the loss in gold is naturally less; and he found on average, a loss of 2.2% on the value of gold and silver. As examples, he found in the copper water (the filtered solution from the precipitated gold) $3.06 per ton of ore treated; and in another case $2.22 in gold and 22c. in silver. In treating concentrate containing dolomite the copper water contained nearly 30c. worth of gold per ton of water. He concludes his remarks upon this point by saying that after the copper had been precipitated by metallic iron the liquid still contained, after standing for a week, 2.5 mg. gold and 10 mg. silver, per cubic foot of solution.

SODA-ASH production of the United States during 1918 was 1,390,628 short tons, valued at $35,635,520, compared with almost exactly the same quantity in 1917, valued at $38,028,000, according to R. C. Wells, of the U. S. Geological Survey. Sales in 1916 were 1,200,000 tons, valued at $18,000,000. These figures do not include sodium carbonate reported in the form of monohydrate and sesquicarbonate, for the production of which exact figures are not available, nor the soda-ash consumed by the manufacturers in their own plants in making caustic soda and other sodium compounds. The quantity of soda ash used for the latter purpose in 1918 is estimated at 664,000 short tons, against 482,000 short tons in 1917. Most of the soda ash is made from salt and limestone, but a small quantity is made in the West from natural sodium carbonate, chiefly that obtained from the water of Owens lake.

The Montana School of Mines

The establishment of the State Bureau of Mines and Metallurgy as a department of the Butte School of Mines, is further evidence of this institution's growing importance to the mining industry of Montana. The Act creating the Bureau was passed by the State legislature last February, and the sum of $20,000 was voted for the two years ending February 28, 1921. It was somewhat remarkable that, while 42 out of 48 States have their own Geological Survey or Bureau of Mines, the important mining State of Montana was not so equipped. The newly-created Bureau has already been called upon to make one or two investigations, and, with Charles H. Clapp, Ph. D., President of the Butte School of Mines as Director, it is safe to say that further useful work will be done. The objects and duties of the Bureau are similar to those of other such institutions, and will be found fully set forth in a Bulletin of the University of Montana, Bureau of Mines and Metallurgy, Series No. 1, which will appear in print in the near future. Suffice it to say that the Bureau is organized into four major departments: Administrative, Geology, Mining, and Metallurgy and Safety, for the purpose of aiding in the development of the mineral resources, and for the assistance and promotion of the mineral industry of the State. The Butte School of Mines is to be enlarged by the erection of new chemical and metallurgical laboratories, for which the sum of $100,000 has been voted by the State legislature and approved by the State Board of Examiners. This addition to the school buildings is in accordance with the plan originally laid out, and the architects are now engaged on the design. The total cost of two new structures will be nearly $200,000. The work of the school, like that of all such institutions, was greatly crippled by the War. The regular courses have now been resumed, however, and the registration of 92 is the largest in the history of the School, which enjoys the distinction of being situated in the world's greatest mining district. For purposes of instruction, the importance of having the Butte mines ''in the back yard'' cannot be over-estimated, while the metallurgical establishments of Anaconda and Great Falls are easily accessible. It goes without saying that, thanks to the liberal co-operation of the mining companies, full use is made of these facilities. During the past week the Junior class made a trip to study the geology and ore deposits of the Judith and Highwood mountains, the coal mines at Roundup, and the smelter and power-plants at Great Falls.

GOLD PRODUCTION of the Dutch East Indies during the past 8 years totaled 47,780,800 florins ($19,207,881). Of this, 80% came from the district of Benkolen on the island of Sumatra. In 1914 Sumatra yielded $2,700,000, and in 1918, $1,490,000. During this period the Celebes yield fell from $490,000 to $337,000.

Power Requirements of Rock-Crushing Plants

By MARK H. REASONER

At this time, where maintenance work is in demand, the question of requirements for rock-crushing is pertinent, and this depends primarily on the characteristics of the power employed. As most quarries are situated where electric power is available, it becomes primarily a question of motors. In the mining districts of the South-West and North this calls for the consumption of a large aggregate of kilowatt-hours supplied from large transmission systems, such as exist so opportunely in Washington, Montana, and California. Probably the largest individual groups of crushing machinery driven by electric motors are within the territories served by such systems.

But it is not alone among the large mining-plants that considerable opportunities exist for the use of electric power in driving crushing machinery. Scattered throughout the length and breadth of this country are thousands of quarries, gravel-pits, commercial rock-crushers, screening-plants, gypsum mills, phosphate and fertilizer plants that depend for their raw material on the rock formation in their vicinity. Nearly all of these are so situated as to secure energy to advantage.

Taking the country as a whole, it will be found that in many places direct-current systems are in use by numerous industries that involve crushing and in such cases they can be readily supplied with direct current, or, in some cases, with a trolley-line in the vicinity, or, in the case of an electrified railway, such as the Chicago, Milwaukee, & St. Paul, from its transmission line, or through a rotary convertor or motor-generator set at the plant where the energy is used. The application of the direct-current motor will not materially alter the horse-powers given in the table below, inasmuch as the latter are only approximate and will be governed by condition of service prevailing in the place where the power is used.

There are two general types of the induction motor that fulfill the usual requirements of rock-crushing plants, namely, the slip-ring and the squirrel-cage types. The former, when furnished with drum-type non-reversible controller and resistance, is suitable for service requiring frequent starting under load, or the starting of loads with high inertia. This motor has a phase-wound rotor and external resistance connected through slip-rings and it is due to this feature that it will start with a high torque and a comparatively small amount of current from the line. The resistance is gradually cut out as the motor comes up to speed, until short-circuited. When the motor reaches full speed the rotor resistance will be almost as low as that of the squirrel-cage type of motor and consequently good operating characteristics will obtain.

The squirrel-cage motor, equipped with a compensator, is extremely simple and built to stand hard service. The absence of a commutator enables it to operate satisfactorily in positions where dust and dirt would prevent the employment of the slip-ring type; but its construction does not enable this type of motor to be started with a very high torque; consequently it is not adapted to certain loads, as for example ball-mills, tube-mills, etc. These mills require from 50 to 80% more power to start than is required for their normal operation.

Broadly speaking there are three conditions to be met with in rock-crushing and metallurgical plants, namely:

1. A complete installation containing no units requiring an abnormal starting torque.

2. An installation that includes one or more elements requiring a large starting torque, but that, for uniformity in operation, should be driven by a single motor.

3. Machines similar to (2) but such as to permit of the units being started or stopped independently.

It is obvious that the squirrel-cage type of motor should be specified in the first instance; the slip-ring type in the second, and a combination of both types in the third.

Ball-mills, tube-mills, and revolving drums (chlorination barrels or similar leaching-drums) are common representatives of the type of machines that require excessive starting torque. Hoisting machinery usually falls in this class also, but such machines as gyratory and jaw-type rock-crushers, rolls, hammer-mills, elevators and conveying machinery, dryers, jigs, concentrating tables, and many forms of roasting or calcining furnaces, can readily be put into motion with squirrel-cage motors. It is always doubtful economy to attempt to use a clutch-pulley to take the place of the proper type of motor, as the additional first cost and upkeep will in most cases show a decided balance in favor of the proper type of motor.

Great care should be exercised in locating motor-drives in dry-crushing plants owing to the presence of dust and grit. While there are some excellent designs of dust-proof motors being manufactured that meet such conditions, the most satisfactory solution of the dust problem where conditions will permit is to extend the drive-shaft to a point that will ensure safety from this evil.

In the foregoing tabulations is given the approximate horse-power required for various classes of crushing and pulverizing machinery. It is sufficiently accurate to serve as a basis for establishing the power requirements.

DEVELOPMENTS in design of internal-combustion engines reveal a peculiar condition, namely, the most efficient type, and one that can utilize the lowest-grade and cheapest of fuels, is only used in this country to the extent of little over 100,000 hp. This is the Diesel engine, which has developed a thermal efficiency of a little over 40% and a fuel economy of 0.45 lb. per brake horsepower. Another point that at first seems hard to realize is that the less efficient type of internal-combustion engine—the Otto cycle—is used extensively and there is possibly more horse-power of this type of engine in operation today than of any other prime-mover.—A. L. Taylor of Utah Society of Engineers.

Industrial Accidents in California

A report on special investigations of permanent injuries, composed largely of a survey of 700 cases where injury is so serious in character as to constitute at least an industrial and economic handicap, has been issued by the Industrial Accident Commission of California. Nearly all these cases are of sufficient duration for time and therapeutical efforts to have made whatever readjustments may be expected. At this time there is, therefore, chance to form a fair judgment of final consequences of the injuries. The findings are not the mere refinements of statistics gathered from reports; the facts included are not local; they are not gathered from a single community, from a particular line of industries, of a special class of workmen. They came from various communities in different parts of the State, and include almost every form of industry from street sweeping to banking. They were obtained at first hand by experienced investigators from the living sources themselves. The investigators met the injured in their homes, their places of employment, or in the offices of the Commission.

The percentage of injuries in the entire 700 cases were as follows: head and face, 4½; eye, 21; arm and hand, 36½; leg and foot, 23; trunk—including spine, 5½; and multiple injuries, 7.

In a classification by age, at the time of injury, there were 28 under 20, 580 over 20 but under 56, and 88 over 56 years.

In a classification by attitude toward injury and general outlook on life the following was found:

	Attitude	Outlook
Cheerful	503	..
Indifferent	75	..
Discouraged	122	..
Optimistic	...	19
Normal	...	606
Pessimistic	...	75

The general averages of all the classifications are:

Whole number under survey	700
Age at time of injury, years	37.8
Wage, before injury, weekly	$22.34
Wage, since injury, weekly	16.60
Disability rating, weeks	139
Compensation, weekly	$13.55
Time lost on account of injury, months	11.95
Number of dependents	2
Average age of children, years	9.5

While general averages often do not convey very definite and helpful information, there is still something about them that makes one wish to find what they are. This table will help very materially in forming a general conception of the conditions that obtain through permanent injury.

CONCENTRATE saved by the Waihi company in New Zealand last year amounted to 2676 tons from 188,998 tons of ore. It assayed 8.83 oz. of gold and 38.75 oz. of silver per ton. By grinding in tube-mills, agitating in pachuca tanks, and filtering in Dehne type presses the extraction was 98.4% of the gold and 95.2% of the silver. In the refinery, 46,758 lb. of precipitate yielded 561,348 oz. of doré bullion. This yielded gold 999.5 and silver 996 fine.

Employment-Management at the Eagle Mines

By ROBERT NYE

For a long time labor conditions at the Eagle mines of the Empire Zinc Co., at Gilman, Colorado, had been unsatisfactory. There had been no strikes and none were threatened, but the labor turn-over had been large and the average efficiency low, although probably no more so than in any other mining district in the Rocky Mountain region. It was recognized that this was primarily due to the great scarcity of labor and its attendant inefficiency. This did not seem, however, a sufficient reason for so many men leaving the company's employ to go to work soon afterward at other mines where the working and living conditions were no better and wages no higher.

The mines are dry, the ventilation much better than the average, and the wages as high as at any mine in the State. Board at the company's hotel was $1.10 per day, and as good as it could be made, at a loss of 45c. per day per man. Most of the single men had steam-heated rooms to themselves, rent-free. The married men lived in four-room houses with electric lights and modern plumbing, for which they paid $12 per month, including water. No restrictions were placed upon the men as to where they should board; some found accommodations in private families, while others lived in their own homes at Red Cliff, three miles away.

The company has a pension system, the benefits of which most of the men consider too remote to interest them. There is also in operation a bonus system by which every employee who has been with the company a full calendar year, receives a percentage of the wages earned during that year. This bonus depends upon the profit for the year, and has ranged from 5 to 15%. It is a highly prized feature with the men.

There is a good public-school at Gilman. The company has a sociological department, which maintains a free kindergarten, library, and reading-room. This department also conducts a club-house where 'soft' drinks, cigars, tobacco, and candy are sold, and pool and cards can be played at any time, and where moving pictures, community singing, dancing, and other social diversions are provided at regular intervals. There is a well-equipped hospital with a physician and trained nurse in regular attendance.

In short, the management felt that they had done about everything they could to make the working and living conditions as healthful and pleasant as the situation of the mines, at an elevation of 8900 ft. above sea-level, permitted.

After consulting the superintendent and foremen it was decided by the management to take the hiring and discharging of all men from the foremen and place it in the hands of an employment-manager. I was selected for this position and entered upon my new duties in January of this year.

Under the old system the foremen of the three mines each hired his own men. Most of it was done during the few minutes after the whistle blew for the shift to go to work at 8 a.m. and before the foreman followed his men underground. He then knew how many men had failed to show up for work. He was always in a hurry and seldom took the time to inquire closely into the past record or qualifications of the applicants for work. The first husky-looking individual who asked for a job usually got it. If he 'made good', all right; if he did not, he was fired and forgotten, often to go to work the next morning at one of the other shafts for another foreman. A man might work a day or two in each of the three mines in one week, and leave without any record being made as to what kind of work he had done.

Under the new system, each foreman telephones to the office, stating the number of men wanted and the kind of work for which they are wanted. When men apply to the foreman for work they are referred to the office and if the foreman is personally acquainted with any of them, or has any information about them, he sends it to the office by note or by telephone. The employment-manager gives each applicant a leisurely friendly interview, during which a large amount of information about the past experience and record of the man is usually brought out. An application card is made out upon which is recorded the man's full name, age, place of birth, if foreign born whether naturalized or not, whether married or single, dependents, name and address of nearest relative, two former employers and position with each, with reasons for leaving, kind of work wanted, experience in any other kind of work, and by whom recommended, if a recommendation is given. Sometimes former employers are written to, depending upon the position wanted. If the applicant has worked for too many different companies during the preceding year or two, he is seldom hired. If he is considered a promising man, he is sent to the company doctor for a thorough physical examination. It is always explained that this examination is for the protection, not only of the company, but of the man himself and the men that he will work with. So far there has not been a single protest against the physical examination. If the applicant passes the doctor's examination, and few fail to do so, he is given a note to the foreman that wants him and another to the steward of the hotel, who assigns him to a room. The date that he starts work, his position, and rate of pay are entered upon his application card. There are blank spaces on the card upon which to enter any transfers he is given, the date and reasons for leaving, when he is separated from his job, together with the degree of satisfaction he gave in each kind of work performed.

When a man quits, the foreman gives him a time-slip, which he takes to the employment-manager, who has a friendly talk with him and finds out his reasons for leaving. If it is found that he has been satisfied with conditions here, but is going to a better job or has other sufficient reasons for going, he is sent away with a blessing. If it develops that he is dissatisfied, and has some complaint to make, he is told to come around later for his check. In the meantime his complaint is investigated and if, as sometimes is the case, it is found to be justified, the cause of complaint is removed if possible and he is given a chance to go back, or he may be given a chance to go to work in a different part of the mine, as seems best in each individual case. In this way many good men have been retained that would otherwise have been lost, among them some of the best men we have. When a man proves unsatisfactory to a foreman much the same procedure follows; the man's story is heard; and if it seems that he has some grounds for complaint and there is a suspicion that a foreman or shift-boss has been giving him the worst of it, he is given a chance under some other boss, and often makes good. In this way the employment-manager becomes a sort of court of appeals. It has been found that foremen and shift-bosses are much more careful and reasonable in their treatment of the men under them since they know that they may be called upon to explain their conduct. They also realize that it is a reflection on their management of the men under them when a man they have turned down, makes good in another part of the mine under another boss.

As the force has only averaged about 250 men, it was seen that the employment-manager's time would not be fully occupied unless he had other duties. Accordingly, he was also made safety and efficiency engineer. This has proved to be a good combination as the two lines of work dovetail together nicely. The regular inspection trips through the mine and mill show under just what conditions each man is working and enables a useful acquaintance to be maintained. It is wonderful how far a few cheery words every few days go toward gaining the confidence of the men and how much easier they make it to decide justly when complaints are forthcoming.

During the three months in which the system has been in force the results have so fully justified the experiment that the management would not consider going back to the old method. In January the labor turn-over was 32.9%, in February 15.35%, and in March 11.58%. In March the turn-over would have been 6.84% if the hotel, with its average of ten employees, had been excluded, and the feeling has grown that kitchen and dining-room help are about as temperamental as opera singers. It is fully realized that labor conditions during the past three months have been abnormal and these figures might not have been duplicated in ordinary times. We are also getting more work per man, although our best men are not working any harder now than they did last year; in other words, we now have a much more efficient force, due to careful selection of new men, than we ever had before.

So far no records have been kept of each man's daily output, but it is hoped that a system for doing it can be evolved soon without adding to the expense or placing too much extra work upon the foremen and shift-bosses. Owing to the nature of the work such records cannot be made absolutely accurate, as, for instance, where a number of men are shoveling together in a stope, but it can be made accurate enough to be of great value to the management and a stimulus to the workers.

The maintenance of an employment department is a comparatively new thing among industrial organizations, but during the past few years the practice has been gaining in favor rapidly among the largest manufacturing and commercial companies. So far as known only a few of the largest mining companies have adopted this method of handling their labor. It is the belief of the management here that it will be advantageous for any mining company employing 150 or more men to have an employment department. Where the force is small the employment-manager can readily add to his duties that of safety and efficiency engineer, take care of camp sanitation, housing of employees, and general welfare work.

BLASTING OLD CONCRETE. Removal of old concrete or masonry is generally done by drilling holes with jumper steel and sledges by hand, then breaking off the material bit by bit with wedges. This is a slow and expensive way. The best, quickest, and cheapest method is by blasting. At first thought, most people would immediately say that explosives could not be used, as they would crack the walls of the building above or damage nearby machinery and be altogether too dangerous. As a matter of fact, explosives can be used with great economy in almost all cases, and with absolute safety. As a general rule, concrete is easily broken by blasting, and experience has shown that the better the concrete, the more easily it can be broken.

In doing this class of work, care must be exercised to see that the holes are properly placed—which, however, is true of all blasting—and that light charges are used. It requires no particular caution or ability to blast old walls of concrete, brick, etc., that are in open places, where there is little likelihood of damage to surrounding property. But it is in cases where the structures to be removed are close to and often are a part of valuable property, machinery, and buildings, that care and a good sense of judgment must be exercised. An explosive of relatively slow heaving action, like ammonia 30 to 40% strength, is best adapted for such work rather than a quick and shattering explosive. The drilling of holes is best done by self-rotating hammer-drills, but when the size of the work does not warrant such equipment, holes can be drilled by hand, using jumper steel or hand-drills and sledge. It is best to demolish the structure by gradual steps or benches, or a little at a time, especially inside or under a building. Six-foot holes are deep enough.

REVIEW OF MINING

COBALT, ONTARIO

RE-WORKING OLD MINES. LABOR. PORCUPINE AND MATACHEWAN GOLDFIELDS

Silver mining has been stimulated greatly by the recent large increase in the price for the metal, and operations are being resumed at many old mines and abandoned prospects, which had been closed. Labor is generally satisfactory. It was feared that the prevailing feeling of unrest might result in a strike, but investigations of the Industrial Relations Commission, which recently sat here, indicate that conditions in that respect are much less serious than was supposed. There is no difference between employers and employees on either wages or hours. The 8-hour day has been adopted, and the advance in the price of silver increases the bonus paid to miners, in addition to the regular wage-scale to $1.25 per day, so that the only point in dispute is the refusal of the mine managers to recognize the union. They are willing, however, to treat with committees representing their own employees, so that there appears to be no present danger of a walk-out.

At South Lorrain, operations will shortly be resumed at the Pittsburg-Lorrain and Wettlaufer mines, the former operating the Wettlaufer mill under lease. Horace Strong, recently of the Crown Reserve, will be in charge. The Keeley mine is also being re-opened.

At Gowganda, the Palmer-Paine, a new company, has acquired control of the property of the former T. C. 177 Mining Co. adjoining the Miller Lake O'Brien, on which considerable work has been done.

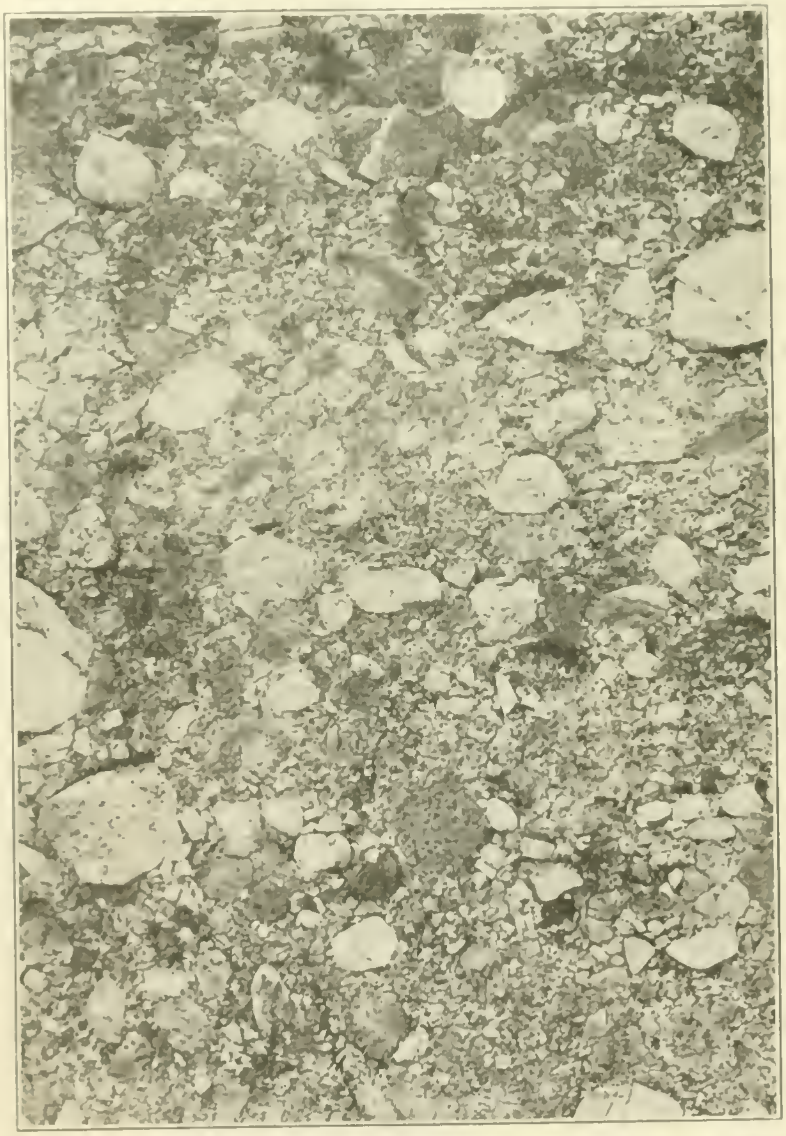
Porcupine. The mill of the Dome Mines is treating 600 tons of $7 ore daily, and gradually increasing its output as more men are being secured.

The cross-cut in Dome Extension has passed through the whole orebody, which is 99 ft. wide, and is stated to return assays of $5.50 per ton.

The mill of the Dome Lake is treating ore from the 600-ft. level extracted from a lens 200 ft. long, carrying $10 ore.

The orebody at the Davidson, which was 34 ft. wide where it was entered by the cross-cut, has widened considerably, and is improving in grade. The management contemplates adding to the mill to bring the capacity to 200 tons per day.

The McIntyre is employing 350 men and treating over 15,000 tons per month. The main shaft is being continued to a depth of 1375 ft., where another main haulage-level will be established. An intermediate level between the present one at 1000 ft. and the 1375-ft. level is under way. An ore-shoot 200 ft. long, worth $23 per ton, has been developed on the 8th level.



THE CONGLOMERATE IN WHICH MANY OF THE SILVER VEINS OF COBALT ARE FOUND

Matachewan. The vertical shaft at the Matachewan (formerly the Otisse) is down 100 ft., and has entered the orebody at a depth of 90 ft. It is over 50 ft. wide, and stated to carry high gold content.

GOLDFIELD, NEVADA

WORK BY THE GOLDFIELD DEVELOPMENT, LONE STAR, AND RED HILL FLORENCE.

A syndicate of New York men, headed by L. E. Whicher, has bought a large interest in the Goldfield Development Co., according to H. G. McMahon, secretary for the company. The sale was made in New York by McMahon, and followed an examination by Walter Harvey Weed of the plans of the Development company to extract a large tonnage of ore in Consolidated ground. More than $100,000 is in the treasury and preliminary underground work is well under way in the Combination, Mohawk, and Red Top mines. F. Dean Bradley, a metallurgist, is in Goldfield to prepare the Consolidated mill for treating this ore, and following his report on the alterations that will be necessary, re-modeling of the plant will be started. Little work will be necessary, and it is estimated that the plant will be ready to treat 1200 tons daily by July 1. The Red Top will be in condition to supply a full tonnage on that date. It may be several months before the Combination will be ready for making an output, but it will not be necessary to take ore from there for a long time. Mr. Weed will return to Goldfield in two weeks.

Assays of $8 and $9 are being obtained in the drift from the bottom of the 58-ft. shaft on the Examiner claim of the Lone Star. At the main workings in the eastern part of the ground the east cross-cut on the 252-ft. level of the Nelligan shaft has been extended 310 ft. The west cross-cut, out 240 ft., has been discontinued. Promising seams are being cut in the east cross-cut, but no driving has been done. This will be continued to cut a vein from which rich ore was shipped by early-day lessees, and if an orebody is not found it is believed that the Nelligan shaft will be abandoned and the shaft on the Examiner claim used for further development.

Following the resignation of J. B. Kendall from the management of the Red Hill Florence and the appointment of H. G. McMahon as his successor, work has been resumed in the 250-ft. south drift on the 500-ft. level. This work is considered important, because it is being done south of the great fault in the Rogers vein, beyond which an orebody has never been opened. Small quantities of ore assaying from $40 to $100 has been found in the drift. South of the fault the vein is 20 ft. wide at a depth of 500 ft. For the past year practically all work done by the Red Hill has been on the 600-ft. level, far to the north of the fault and nearly under the rich ore-shoot in the Florence Divide lease, formerly the Witt-Brandon. This was done in the Red King claim of the Florence Goldfield, leased by the Red Hill. All work at this depth has been stopped, as the entire territory has been explored without an orebody being found. The Red Hill also is exploiting the Rogers vein on the 150 and 329-ft. levels

MEDFORD, OREGON

NOTES ON THE COPPER MINES.

The superintendent, Jerome A. Hilbert, of the Blue Ledge mine at Copper, California, was a visitor at Medford last week, and reports that everything is moving well at the mine, where they have 25 men employed mining and shipping 500 tons of ore per month, which is shipped to the Tacoma smelter, Washington. This ore averages 14.5% copper, 6 oz. silver, and $2 gold per ton. Copper at 15 cents and silver at $1 per ounce brings the value to $51.50 per ton. This is a good grade of ore, but the first 30 miles of its journey to smelter—mine to Jacksonville, Oregon, the rail head—it is conveyed by team 7 miles, auto-truck 23 miles, which costs $12 per ton, and runs into $6000 per month, that this mine alone pays out for freight on ore, besides the supplies and passenger traffic that is carried. This is an attractive item for any railroad to consider when it is remembered that it is claimed by those familiar with the district that there is a number of undeveloped properties with exposures fully as good as the Blue Ledge was at the same stage of development, but are handicapped by want of capital for development and wagon-roads. Among the good properties are the Bloomfield, Blue Canyon, Copper King, St. Albans, and Great Northern groups.

John Dixon and associates have met with good results at the Buck and Sullivan copper claims, which are situated on Squaw Lake creek, 6 miles north of the Blue Ledge mine.

O. F. Tainer and associates have just discovered and located a deposit of 9% copper ore, besides gold and silver. This is in the head of the Elliott Creek region north-east from the Blue Ledge mine.

E. W. Cooper of Sams valley, 15 miles north of Medford, is reported to be making good progress in driving the new tunnel on the Gold Wedge mine. This is intended to cut the vein at considerable depth, as milling ore of satisfactory grade in upper workings is all worked out.

The management of the Copper Lode Association announces its intention to resume work soon. They have an attractive copper prospect, equipped with a 30-hp. gasoline engine, air-compressor, and hoist. This property is 12 miles south of Jacksonville and is reached by a good auto-road.

The improving metal and mineral markets are shown by an increased amount of assaying, as reported by Campbell & Liljegran, of Medford.

SILVERTON, COLORADO

WAGE AGREEMENT.—GENERAL NOTES.

While this district is quiet, settlement of the wage-scale and the rising price of metal give encouragement to operators to continue development and get ready to ship ore. The outlook is favorable for a gradually increasing production. The Sunnyside M. & M. Co. has decided to re-build the structures destroyed by fire, this decision being reached after the wage agreement was made. While there has been some dissatisfaction over the new wage-scale, the general attitude is one of acceptance without complaint. Following is the agreement

(1) Eight hours constitute a day's labor in and around mines, mills, tramways, and smelters.

(2) $4.25 shall constitute a day's wage with the exception of unskilled labor on the surface, which shall be $4.

(3) All classes of labor working in wet places, where rubber clothing is required, 50 cents additional.

(4) For sinking and raising, 50 cents additional.

(5) This scale shall be based upon $1.25 per day for board.

(6) Pay-day twice a month.

There is a mutual understanding that this will continue until the increase in metal prices permits a higher scale. The wages to be paid are as under:

Mine Men	
Machine-men	$5.00
Machine-men helpers	4.50
Timber-men	4.75
Timber-men helpers	4.25
Engineers	5.00
Station tenders	4.25
Blacksmiths	5.00
Blacksmith's helpers	4.25
Blasters	4.50
Firemen	4.50
Mule-drivers	4.25
Trammers	4.25
Shovelers	4.25

Tramway Men	
Oilers and linemen	$5.00
Gripmen	4.50
Bucket-men	4.50

Mill-Men	
Repairmen	$5.25
Oil-flotation operators	4.75
All other operators	4.50
Mud-pullers	4.25
Crushermen	4.25
Roustabouts	4.25

The Henrietta Copper Co. is getting its properties in condition for extraction of ore. During the close last season this mine yielded some high-grade ore, but the low market caused a stoppage of shipments.

The Radiant Mining Co. is starting men on development in Ruby basin. The road is now opened from the mines to Burro bridge, on the Silverton northern line, Red Mountain branch.

The Anvil Leasing Co. is developing and shipping from the Emerald lode, also known as the Coming Wonder mine. A new vein carrying good values in silver has been opened.

The Dora Consolidated has leased a portion of its workings, the Boston tunnel, to local men, and the lessees are shipping.

The Caledonian is to resume operations this season.

The Iowa Tiger has its mill operating again after a long delay due to a burned-out transformer, and Iowa Tiger and Mayflower ores are being treated. Snow slides recently broke down all of the towers on the Mayflower tram, but the damage has been repaired.

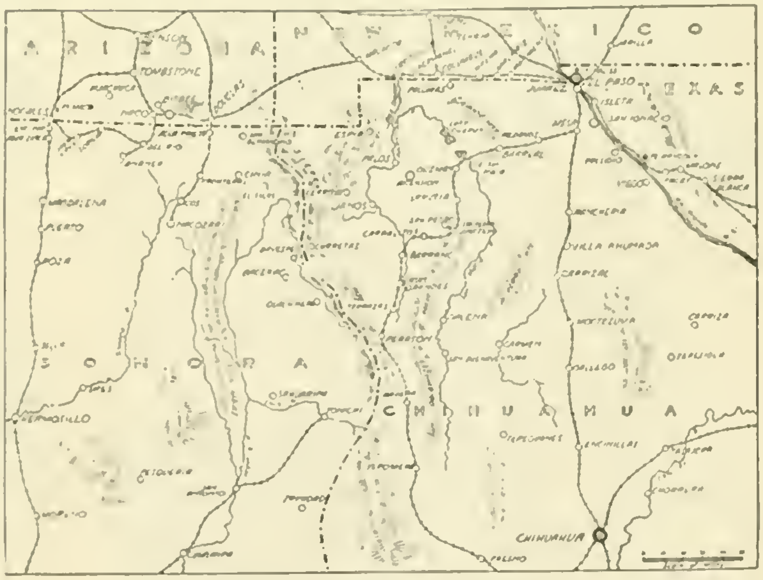
The Gladstone branch of the Silverton Northern is being opened. While the main object is to get in a large amount of machinery needed to complete the Gold King Extension Mining Co.'s mill, the early opening of the road will permit a number of smaller producers to ship earlier than usual.

CANANEA, MEXICO

TROUBLES AND TRIBULATIONS IN SONORA, MEXICO

On account of raids by Yaqui Indians, the Villa element getting busy once more, and the numerous embarassing State and national labor and mining laws in operation in Sonora, the lot of the mine operator is not particularly a happy one, no matter how rich or favored his property may be.

The Yaquis, supposedly in alliance with Villa, have been on the warpath in Sonora for several months, and lately have extended their activities to the southern part of the Moctezuma district of Sonora. Among recent outrages committed against mining men may be mentioned the attack of Indians upon a motor-truck train on the road between La Colorado and San Xavier while it was engaged in freighting ore from La Colorado mine to Hermosillo. H. S. White, an American chauffuer of one of the trucks, was killed, as were several of the Mexican freight-handlers riding on the trucks. The Indians attacked from ambush. The truck train was a comparatively new feature with La Colorado mine, having been in operation only a few months. La Colorado is owned and operated by W. C. Laughlin and E. C. Schroeter of New York, and it is reputed to be one of the richest silver mines in Sonora, but contains such complex ore that considerable technical skill is required. This was found out to their cost when State officials of Sonora during the course of a quarrel with the owners of the mine over taxes attempted to operate by 'hit or miss' methods. As a result, instead of showing a profit as it should, reports from Hermosillo at the time said that the Mexicans were disgusted to find that there was a distinct loss.



PART OF SONORA AND CHIHUAHUA

On the same day that the attack on the truck train of La Colorado mine in the south-central part of Sonora took place, another band of 60 Yaquis entered the camp of the Monte Cristo mine, 30 miles south of Moctezuma, capital or county seat of the Moctezuma district, and after killing six Mexican inhabitants and driving the remainder into the hills, proceeded to rob the camp. Arms, explosives, food, and valuables of all kinds were stolen. James Lord, manager of the property, was robbed of the clothing he wore, but, as he had taken no part in the fight that marked the entry of the Indians, his life was spared. The Indians operated under a military system with officers in command instead of chiefs.

Earlier in the month, Cananea was the centre of trouble when a band of 22 Mexicans seized the town, killed five policemen, including the chief, liberated all prisoners in the two jails, forced the cashier of the Banco Mercantil to open the vaults, and thus obtained $40,000 in gold, looted four stores and rode out of town. Subsequent reports told of the death of seven of the band in fights with pursuing rural police, while one was captured at Agua Prieta, taken to Cananea and hanged to a telephone pole. The men declared themselves to be supporters of Villa, and several of them are said to have escaped into Chihuahua with their loot.

Another similar case, involving considerable suffering but allowing its victim to escape with his life, was that of Franklin B. Harding, chief consulting engineer for the Chicago Exploration & Development Co., who arrived at Douglas on May 31, from Helamer, on the Sonora-Chihuahua boundary, after a brush with bandits entailing enough excitement to last him a life time. Under the leadership of Arturo Lopez, a band of Villa followers raided the camp, intent upon getting hold of a cache of arms and ammunition they had been informed Harding had concealed. His protestation that there was nothing of the kind there resulted in nothing but maltreatment, he said. The appeals of the Mexican foreman and some of the Mexican miners, of which the company employs 75, resulted in no alleviation of his inquisition, while his life was threatened momentarily by the bandits. Looting the commissary and taking such moveable property as they wished to carry with them, the Villistas rode off with Harding as their prisoner. At the little pueblo of Mors, Chihuahua, Harding was liberated after being beaten and having almost all of his clothing and his shoes taken from him. The shoes, after the soles had been cut out, were returned to him and he was instructed to leave at once. He arrived in Agua Prieta after making a hike of more than 75 miles. From Agua Prieta, after resting a short time, Mr. Harding went to Hermosillo with the avowed intention of obtaining a military guard for the mine, then returning to Helamer and resuming operation of the silver property of which he is manager at the present time. Incidentally, after obtaining action of some sort from the Sonora government, he will lay his case before the State Department of the United States.

During 1918, the Greene Cananea Copper Co. sold metals worth $10,381,348, and had other revenue amounting to $520,418. The profit was $3,434,629, after deducting $1,139,853 for Mexican taxes and $528,734 for depreciation. Dividends amounted to $4,000,000. Current assets are $8,032,618, and liabilities $905,001. The surplus of $8,048,652 at the end of 1917 was reduced to $7,483,272. Development totaled 70,045 ft., and new ore exposed equaled that extracted. The mill concentrated 289,098 tons, and the smelter reduced 902,520 tons of copper-bearing material from all sources. The yield from company ores was 52,694,731 lb. of copper, 1,666,993 oz. of silver, and 9846 oz. of gold, equal to an extraction of 2.42% copper, 1.502 oz. silver, and 0.008 oz. gold. Many improvements were made at the mines, mill, smelter, and railway. There were 170 Americans and 4015 Mexicans employed. The cost of production was 15.082 cents per pound of copper. T. Evans is general superintendent.

HOUGHTON, MICHIGAN

COPPER SALES AND OUTPUT.—GENERAL BUSINESS CONDITIONS.

Sales of copper produced in this region last week were equal to the current output, but not cutting into the surplus. The most encouraging feature is the fact that Calumet & Hecla has sold some metal at 17 cents per pound. The 50% curtailment in capacity of this group will be evident in the June outputs. The total for the current month will be lower than at any time since the strike in 1913, although this will not show in the figures from the Mohawk, Wolverine, Quincy, or Copper Range mines—Baltic, Champion, and Trimountain—as these properties are producing at approximately 85% of normal.

General business in the Copper Country is good, despite the departure of hundreds of miners and trammers, the result of closing many of the C. & H. subsidiaries and part operation at all of the C. & H. mines. Bank deposits are larger than ever before. This money is mainly the savings of employees of the copper mines. Michigan has been on the prohibition list for two years, this being a considerable factor in saving money.

BISBEE, ARIZONA

FIRE PREVENTION.—COPPER QUEEN PENSIONS.

As a result of several fires during the last year and a half, fire prevention is occupying considerable attention among the larger mining companies of Arizona. The Copper Queen recently installed an electric fire-alarm system, connected with the Bisbee city system. Signals are given by the big siren at the Czar shaft, which also gives city alarms. The Bisbee apparatus will respond.—The Arizona Copper Co. at Clifton recently retimbered its No. 6 shaft and put in a sprinkler system.

The Copper Queen annuity plan is being brought to the attention of employees through a recently established publicity department. Men who have been with the company for 15 years or more, or who are disqualified from active work by physical disability, are entitled to annuities of 2% of the average wage of the individual for the three years previous to retirement, multiplied by the number of years he was in service. The men make no contribution to this fund.

THE MINING SUMMARY

ALASKA

The U. S. Geological Survey has just issued two new bulletins on Alaska. No. 664, by G. C. Martin, discusses the Nenana coalfield; and No. 683, by G. L. Harrington, covers the Anvik-Andreafski region, including the Marshall district.

These publications are well illustrated, as usual.

The coal of Nenana occurs in many beds of different thickness, the thickest being perhaps 30 or 35 ft., which are distributed rather uniformly through the coal measures. At least 12 beds are of workable thickness, and six or more are over 20 ft. The coal is a lignite of good grade, the fixed carbon ranging from 27.83 to 41.71%, and ash 4.51 to 39.88%. The coal of this field can be brought to the present assured markets only over the Government railroad, now under construction.

The Anvik-Andreafski region embraces the territory west and north of the lower Yukon river between rivers of these names, and an extensive area of low-lying country immediately contiguous to the Yukon on its east and south sides. The first placer gold was produced in 1914, the output being $15,000 from two properties; then $25,000 in 1915; $270,000 in 1916, and $425,000 in 1917, the last from six claims on Willow creek. The first lode claims were staked in 1914.

Anchorage.—According to J. L. McPherson, engineer with the Alaskan Engineering Commission, who appeared before the House Appropriation Committee at Washington, the success of the Government railroad is dependent on its early completion to the navigable waters of the interior. This is necessary to make it possible for those pioneers in the interior to build homes and industries, and attract other pioneers to that region. So far, everybody has simply been 'creaming' the richer placer deposits at a great economic loss. The only way that condition can be righted is by the economic means of transportation, which will be afforded by the new railroad. Its major revenue for a number of years will be from the through traffic the road will carry; the longer the project is delayed in completion the less the traffic will be upon its completion. On the line, 252 of the 437 miles of new work has been done, and when joined with existing lines the connected mileage of the Territory would total 545. Large amounts of grading and other work also have been done on the unfinished part. In order that construction work may not be temporarily interrupted, the House approved an appropriation of $1,964,350 for the work in the general deficiency bill sent to the Senate last week. The present force of 1500 men will be doubled in June.

Juneau.—Alaska Gastineau during the first quarter of 1919 made a loss of $106,784, compared with $78,381 in the last period of 1918. The mill treated 497,469 tons of 79.6-cent ore, recovering 76.76%, at a cost of 83 cents per ton. The comparative figures for the previous term were 287,571 tons, 79.1 cents, 80.22%, and $1.06 per ton.

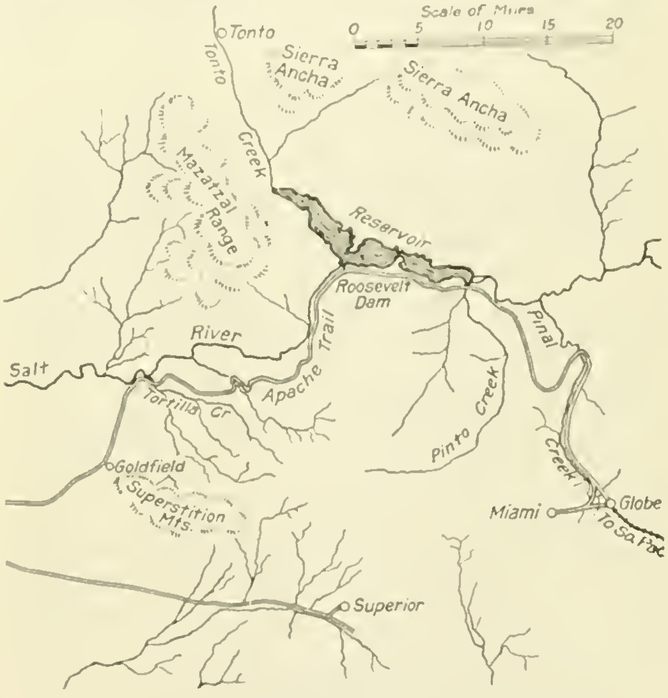
Alaska Gastineau during May treated 202,377 tons of 80.1 cent ore, recovering 77.65%. Tonnages since January, inclusive, have beer 151,515; 162,400; 183,550; 167,630; and 202,377.

Kennecott.—The Kennecott Copper Corporation distributed 50 cents a share on June 30. This amounts to $1,393,339, and makes $2,786,678 for 1919, and $45,143,675 to date.

ARIZONA

Chloride.—It is reported that rich gold ore has been struck 4 miles north of the Pilgrim mine and 12 miles west of Chloride. The strike is causing considerable local excitement.

Miami.—One of the four plants of the Salt River Valley Water Users' Association at the Roosevelt dam, which supply electric power energy to mines in this district and to the city of Phoenix, was tied-up by a strike on June 7, when the Association refused a demand for a closed shop and increased wages.



PART OF ARIZONA, SHOWING PART OF SOURCE OF POWER FOR THE MIAMI-GLOBE MINES.

Bisbee.—A new electric hoist is being put in the C & C shaft of the Copper Queen Branch of Phelps Dodge Corporation, in order to reduce sinking costs. Increased operations at Sacramento hill have necessitated additions of machinery at the machine-shops. In order to improve underground ventilation, plans and specifications are being drawn for the necessary equipment, which it is estimated will cost $30,000.

Phoenix.—For 1000,000 shares in the Kay Copper Co., S. J. Tribolet of this place received $166,000 cash last week. George Long, well known at Oatman, has taken an option on half of Tribolet's controlling interest. The mine is 40 miles north of Phoenix, near the Agua Fria river. Some rich shoots of ore have been developed to a depth of

600 ft., reserves being valued at several millions. Later on a concentrating plant and reverberatory furnace may be erected.

Superior.—The Magma Copper Co. has taken over the last of the Queen Copper Co.'s claims for $75,000.

Tucson.—The Lowell Gold M. & D. Co. has a mill in Horseshoe basin of the Quijatoas. The gold is said to be high-grade, and treatment is expected to commence within 60 days.

After sampling and testing the ore of the Banner, Olympic, and Hughs claims in the Sierrita mountains, they have been leased by F. Hereford and J. R. Hubbard. A mill has been constructed to treat the large quantity of low-grade silver ore that has been developed, as well as the dumps.

The Jimmie Lee property, one of the oldest patented properties in the State, has been bonded. It produced a lot of silver in the past.

Winkelman.—The Azlan Gold Syndicate, operating a property of 7 claims 7 miles from Winkelman, has recently opened some rich gold ore. Specimens are on exhibit at the Tucson Chamber of Commerce. Foundations for a mill on the Arizona Eastern Railroad are being constructed. An aerial tram from the mine to the mill, 4 miles away, is being planned. This property is controlled by H. A. Whitcomb and Eastern capitalists.

CALIFORNIA

Almaden.—Fire at the New Almaden quicksilver mines last week destroyed a great deal of the surface plant.

Caliente.—A. Trojanovich of Globe, Arizona, associated with George Kingdon, general manager for the United Verde Extension Mining Co., and several New York capitalists, have recently formed the Zenda Gold Mining Co. to operate the Zenda mine at Caliente, Kern county, California. It is the intention of Mr. Trojanovich to move the present mill up to the mine and erect a 150-ton cyanide mill, consisting of Marcy ball-mill, Dorr counter-current system of cyanidation, and other machinery, immediately. He now has men constructing a road to the mine.

The Cowboy mine at Caliente has been recently bonded by Walter X. Osborn, who will erect a small cyanide mill there and re-open and develop the mine.

Grass Valley.—The Norambagua mine, an old producer in the Forest Springs district, four miles west of this place, is to be re-opened at once. An entirely new plant is to be erected, including power lines, compressor, and hoist. The mine was closed because of war conditions, but a large body of ore had been opened. C. T. Green, the former manager, is in charge for Eastern capital.

Placerville.—The Gold Ridge district, 6 miles by road from this place, is attracting attention. Gold Ridge extends east and west for two miles or more between Rock Creek canyon on the east and Kelsey canyon (on which is Kelsey camp) on the west; and rises abruptly from the South Fork of the American river, which flows sinuously westward along its south base. The altitude of the river is 1100 ft. above mean sea-level. Down the south slope of the ridge there are three deep ravines known as Dark canyon, Ladies canyon, and Texas ravine; the last being farthest west and heads on the north side of and near the top of the ridge. Large quantities of gold were recovered from these ravines in the 'fifties by early-day miners; especially from the Texas ravine, as is evidenced by the extensive old-time placer workings along the head of the ravine. The Kelsey Gold & Silver Mining Co. owns several quartz claims north from the river across the west end of the Gold Ridge. It is reported that arrangements have been completed to erect a cyanide mill, air-drills, etc., to cost $25,000. E. N. Finn of New York recently inspected the property. Just east of the Kelsey is the Manzaneta mine, being developed by E. N. Fessler. He has a small mill and concentrator at work. Another group of lode claims is the Marshall, which has yielded a good deal of gold.

Sierra City.—The vein in the Cleveland mine is so promising that 10 stamps are being added to the mill, thus doubling its capacity. At the Monarch the output is satisfactory, and 25 men are at work. Both mines are owned by R. G. Gillespie, an oil operator of Pittsburgh, Pennsylvania, and managed by S. E. Montgomery.

Jackson.—The Gwin Mine Development Co. has decided to sell its entire surface plant preparatory to a complete abandonment of the property. The mine was bought from Wm. M. Gwin of San Francisco 20 years ago by the late F. F. Thomas, C. M. Belshaw, and others, who erected a complete 100-stamp mill, a large double-drum hoist, steel head-frame, compressor plant, etc. The property paid dividends for a few years, and it was during that period that a temporary hoist was replaced by a powerful one and 60 stamps added to the 40 then dropping. The large body of ore upon which the company's hopes had been based suddenly gave out, and assessments were levied regularly for a number of years. Shares fell from $11 to almost nothing. After a few years of extensive prospecting, which developed small and quickly worked out bunches of ore, the mine was closed, and for years has been in charge of a watchman. The disposition of the plant is in the hands of the Gwin Mine Sales Co., organized for that purpose.

Washington.—The 40-stamp mill, machine-shop, blacksmith-shop, compressor-building, and several other structures at the Gaston mine, 7 miles above Washington, were destroyed by fire on June 4. The loss is placed at $20,000, but the amount of insurance is not known. The Gaston has been a large gold producer, and re-opening of the mine commenced on May 1 in charge of W. L. Williamson. W. F. McCutcheon, an attorney of San Francisco, is the owner.

COLORADO

Cripple Creek.—Gold output of the district in May was $691,861 from 65,376 tons of ore.

Idaho Springs.—A number of mines are being re-opened in this district, especial attention being directed to silver properties.

Telluride.—The Radium Luminous Material Co. is trying a large tractor for hauling trucks loaded with ore from the Paradox valley to rail. If successful it will result in a large saving in haulage charges. This company and the Radium Company of Colorado are involved in litigation over the Phonograph lode in the East Paradox section. The district is active and the demand for men exceeds the supply.

The Mount Blaine Oil Shale Products Co. has one unit in operation and is at present treating the shale at De Beque.

MONTANA

Butte.—Davis-Daly has cut 6 ft. of 12.75% copper ore in a cross-cut north-west of the fault at 2500 ft. depth in its Colorado mine.

The report of Butte & Superior for the first quarter of 1919 shows a loss of $116,379, compared with $96,507 in the previous period. The average price for spelter was 6.189 cents per pound, compared with 7.893 cents in the preceding term. Only 71,298 tons of 15.436% zinc and 6.71 oz. silver ore was treated, a drop of nearly 40,000 tons. The 19,307 tons of concentrate averaged 54.5% zinc, this being 1.86% higher grade. The total zinc content was 22,044,540 lb., and silver, 424,000 oz. Costs were reduced from $11.86 to $10.77 per ton. Development did not reveal anything of particular importance. Reserves were slightly lower.

The Butte East Slope Mining Co. is preparing to resume work at its property 8 miles east of Butte. Ore will be sent to smelter soon, as there is a 30-in. shoot opened. Where the vein was cut it assayed $8 in silver and gold across 23 ft. E. P. Lanas is in charge.

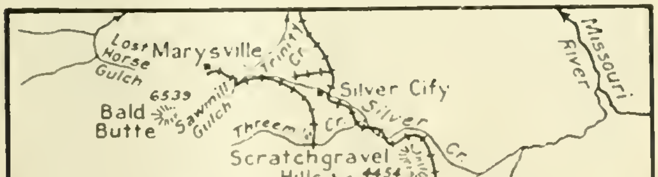
The Diamond mine of the Anaconda company was shut-down last week on account of a lack of skilled men. During the suspension the shaft will be fire-proofed with cement. The Badger State mine, which was closed through an accident to the hoist, has resumed work.

Anaconda produced 13,500,000 lb. of copper during May. This is a little less than half of normal. The company has reduced the compensation of salaried officers by 10%. Officials who were receiving $300 or less a month have had their salaries raised four times, equal to 30%, within the past few months.

Eddy.—The Jewel M. & M. Co. has opened No. 3 orebody in No. 2 tunnel. The first shoot was 80 ft. long, the second, 125 ft., and the third, so far, 85 ft. The ore carries silver and lead. A 200-hp. Pelton water-wheel has been ordered to drive a generator, and a Buffalo blower is being put in for ventilation. A. G. Amsbury is vice-president.

Elkhorn.—The Boston & Montana Development Co. has issued a 16-page booklet illustrating the work being done. The first trains over the Montana Southern line to Elkhorn are expected to run this month. Shipments of 100 tons daily will then commence. The mill contract has been let and it should be ready by November. Underground workings total 11,000 ft. on the 1000-ft. or main tunnel-level, and a large quantity of ore has been exposed. A test on 100 tons of ore made by the General Engineering Co. at Salt Lake City recovered 27.77 tons of concentrate, which assayed $8.20 gold, $48.21 silver, $7.25 lead, and $14.70 copper, a total of $78.36 per ton. A test by O. B. Hoffstrand checked this very closely.

Helena.—Representative mining men of Montana, particularly from districts contiguous to Helena, met here last week to discuss means by which the known and undeveloped areas might be aided and exploited. L. S. Ropes was chairman of the meeting. What most of the local mines require is a treatment plant on each property, instead of the expensive system of sending ore to smelters. Mr. Ropes contributed some general observations on the Helena district to the 'Montana Record-Herald.' Current production is negligible, due to past factors, such as the drop in silver in the 'nineties, failure of the First National bank at Helena, which tied up many properties in litigation, and subsequent abandonment of properties of merit. There is only one mine in the region that is 1500 ft. deep, and out of a list of 217 mines not six are down 1000 ft. Nobody can say whether these mines were worked out or 'knocked' out. A State geologist is required, and if there had been one this region would not have lain disregarded. A conservative estimate of production from 161 of the 217 mines listed is $162,815,000, and from 35 of the 83 placers $69,425,000, a total of $232,240,000. This is considered to be $40,000,000 low. Now that silver is high, the district should attract attention for this metal alone. Bulletin 527 of the U. S. Geological Survey, by Adolph Knopf, issued in 1913, covers the Helena region thoroughly.



PART OF MONTANA, SHOWING DISTRICTS CONTIGUOUS TO HELENA.

Kendall.—The Barnes-King Development Co. made a profit of $23,647 during the first quarter of the current year. A dividend of 10 cents per share, $40,000, was paid on May 15. This makes $80,000 for 1919 and $340,000 to date. The balance of $131,037 at the end of 1918 was reduced to $92,010 at the end of March, plus $50,000 in Liberty Bonds. The mines yielded $179,050 of gold from 19,722 tons of ore. Development amounted to 4068 ft. An option was taken on the Silver Bullion claims in the Judith mountains, 10 miles from Kendall. The property is a prospect, but encouraging. The terms are $5000 in one year and $70,000 two years later, and a royalty of 15% on all ore treated during the interim. The April output was $59,000.

NEVADA

Ely.—The Nevada Consolidated mines and works are at about 50% capacity. There is said to be considerable activity at Cherry Creek and Ward.

Gold Circle.—It is reported that rich gold ore has been found in the Berry brothers property here, just over the Humboldt County line in Elko county, 5 miles north-east of Golconda.

Mina.—According to J. P. Hart, of the Tonopah Extension Mining Co., the Simon lead mine, 22 miles from Mina, was originally discovered 50 years ago. At various periods since that time it has been worked in a small way, and judging from the size of the old stopes, all of which are at shallow depth under the surface croppings, a considerable quantity of ore was taken out and shipped to smelters. The foot-wall is in limestone, with rhyolite formation in the hanging wall. The vein has been cross-cut at the 230 and 300-ft. levels, and the new cross-cut on the 405-ft. level is in ore 25 ft. showing a full face of solid sulphide ore. The 230 cross-cut shows the vein to be 70 ft. wide on that level, 30 ft. of which is carbonate and 40 ft. sulphide. The entire 70 ft. averages $20 per ton. Drifts have been driven 100 ft. in each direction on the hanging wall side, with the same grade of ore persisting. The crosscut shows the vein to have entered the real sulphide zone. The width on the 300 level is 77 ft., and this is a solid mass of glistening sulphides of lead and zinc, carrying in addition 7½ oz. of silver per ton. At no point across the 77 ft. is there a single indication of any waste.

Rochester.—The Nevada Packard is putting in a Marcy mill to replace the old ball-mill. The plant will then treat 130 tons of ore daily. Costs in April were reduced to $4.28 per ton.

Tonopah.—The Tonopah Belmont Development Co. pays a dividend of 10 cents a share, $150,000, on July 1. This makes $300,000 for 1919 and $10,018,063 to date. The Belmont has cut the downward extension of the South vein on the 1166-ft. level. This development is of great value to the life of the mine. So far there is 5 ft. of fair-grade ore. On the 1300-ft. level the drift shows 4½ ft. of good ore.

UTAH

Alta.—This district is now shipping a lot of ore, one day last week 160 tons was carried over the railway. The Michigan-Utah is mining 40 to 50 tons daily, while the Cardiff, Woodlawn, and others have a good deal awaiting transport.

Park City.—A meeting of 300 miners was held here on June 1, and 86 voted to call off the strike. Another general meeting of all concerned was to be held on the next day.

Tintic.—The Tintic Standard company may erect a mill to concentrate its silver-lead ore. Tests have been made on the ore recently.

CANADA.

British Columbia

Rossland.—The Le Roi No. 2 mine from September 30, 1918, to the end of February 1919, has shipped 7500 tons of ore, which realized $82,000. The expenditure was $56,000. In that part of the property known as No. 1 mine, orebodies of considerable promise have been found. On the south Rodney vein the winze is down to the 1950-ft. level, and is clear of the dike and into favorable mineralized ground.

Sandon.—The Silversmith company expected to resume milling early in May, treating from 80 to 100 tons of silver-zinc ore daily. Developments are reported to be very satisfactory.

Silverton.—The Standard Silver-Lead Mining Co. made a profit of $114,764 in 1918, compared with $377,494 in 1917. The surplus increased from $202,801 to $317,565. No dividends were paid, while $300,000 was distributed in 1917. Silver-lead ore sold realized $112,898, and zinc ore $227,338. The total in 1917 was $881,616.

Victoria.—It is reported by G. C. Mackenzie, late of the Canadian Geological Survey at Ottawa, that all available information relating to the manganese deposits of the Cowichan district, Vancouver Island, will be published shortly by the Canadian Munition Resources Commission.

The Bowena copper mine, on Bowena island, under lease to C. W. Tipping, is to have a concentrating plant, instructions having been given for its erection.

Ontario

Matachewan.—At the Otisee gold mine there are 30 men employed. A shaft is being sunk to 200 ft. Machinery taken to the property last year is ready for erection. During the coming summer the water route from Elk lake will be used to transport men and supplies to Matachewan.

Porcupine.—The West Dome mine, closed since the disastrous forest fire of July 11, 1911, whereby 25 people taking refuge in the shaft were asphyxiated, is to be re-opened.

Quebec

Amos.—The new mill at the Indian Peninsula Molybdenite mine in north-western Quebec is nearly ready. The flotation plant has a capacity of 50 tons daily. The property is operated by the Penn-Canadian Mines of Cobalt, Ontario.

MEXICO

Mexico

El Oro.—Esperanza in March treated 12,547 tons of ore and 11,540 tons of tailing for a profit of $17,000. The February profit was slightly under this sum.

KOREA

Unsan.—Oriental Consolidated extracted gold worth $90,530 during May. This is less than normal by $10,000.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. J. Loring went to Boston on June 7.

Gelasio Caetani was in London recently.

Fred Searls, Jr., was in London recently, on leave from Germany.

Frank Cameron has returned to Salt Lake City from Rancagua, in Chile.

Morton Webber is at the Palace Hotel, on his return from Lower California.

George J. Bancroft passed through San Francisco on his way to Denver from Idaho.

Malcolm Roberts, manager of the Aramayo-Francke mines in Bolivia, is in England.

James M. Hyde has been appointed Professor of Metallurgy at Stanford University.

Bruno V. Nordberg has returned to Milwaukee after a visit to the Michigan copper region.

J. C. Ray, Captain commanding the 544th Engineers, has returned from France to Palo Alto, California.

Mark L. Requa has resigned as Federal Oil Administrator and returned from Washington to San Francisco.

Arthur W. Stevens has gone to Mohave, California, to take charge of the Quartz Hill silver mine in the Old Woman mountains.

Horace V. Winchell, President of the Institute, delivered an address before the Montana State School of Mines at Butte on June 4.

Heath M. Robinson has resigned from the U. S. Geological Survey and is now employed by F. Julius Fohs, consulting oil geologist, in New York.

Rush T. Sill, of Sill & Sill, is leaving Seattle on June 14 for the Willow Creek district, Alaska, where he will be engaged in professional work.

Walter X. Osborn has resigned from the Superior & Boston Copper Co. at Copper Hill, Arizona, to operate the Cowboy mine at Caliente, California, which he has recently purchased.

Calvert Townley, assistant to the president of the Westinghouse Electric & Manufacturing Co., was elected president of the American Institute of Electrical Engineers at New York.

On June 6 the Editor received a cablegram from **Major Ernest B. Lighthill** conveying the greetings of those attending the 42nd annual dinner of Royal School of Mines men in London to their fellow alumni in the United States.

Maxwell W. Atwater died on June 4 in the hospital of the Mayo brothers at Rochester, Minnesota. He was only 42 years of age and at the time of his death was manager for the Davis-Daly Copper Co. at Butte, Montana. He was a younger brother of R. M. Atwater, of New York. His untimely end will grieve many in the profession, of which he was an honored member.

The U. S. Bureau of Mines makes the following announcements:

F. B. Tough, petroleum technologist, left San Francisco on June 2 to take charge of co-operative work being carried on by the Bureau with the Midwest Refining Co. and the Ohio Oil Co. in Wyoming.——**C. P. Bowie**, petroleum engineer, has returned recently to San Francisco from a trip through the oilfields of Oklahoma and Texas.——**E. W. Wagy**, petroleum engineer, is in Illinois, studying the methods of production used by various oil operators in that region.

THE METAL MARKET

METAL PRICES

San Francisco, June 10

Aluminum-dust, cents per pound....	50—60
Antimony, cents per pound	8.50
Copper, electrolytic, cents per pound	17.50
Lead, pig, cents per pound.........	5½—6½
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce ..	$115
Quicksilver per flask of 75 lb	$92
Spelter, cents per pound	7¾
Zinc-dust, cents per pound	10—12

EASTERN METAL MARKET

(By wire from New York)

June 10.—Copper is strong and higher. Lead is quiet but steady. Spelter is more active and advancing.

COPPER

Prices of electrolytic in New York, in cents per pound.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

Samuel Montagu & Co. of London, writing on May 15, discusses the silver market since the lifting of all restrictions thus:

The immediate effect upon the market, which had been in a state of suspended animation for many months, was great. No available stock of silver existed from which the Continental [European] demands, which instantly set in, could be supplied, for the good reason that loyal adherence to the known wishes of the [British] authorities had eliminated the possibility of any stock composed of speculative holdings. As a consequence, the price moved at a speed absolutely without precedent. It leaped in one bound 4⅞d. on May 9 from 48⅝d. to 53½d., at which it was officially quoted 'buyers', both for cash and for forward delivery. On the 10th, 58d. for cash delivery and 57⅝d. for forward delivery were reached. The quotation of 58d. is a record since January 1877.

The following prices, in pence, at any advance on which the principal silver coins (full weight-loco London) would show a profit when melted, are of interest, though it should be remembered that with the exception of India and the United Kingdom, the amount of such coins in circulation is comparatively small: Indian rupees (at 1s.8d.), 53.81 pence; United States dollar, 58.9; Dutch 2½ guilder, 60.45; French 5-franc piece and similar coin, 60.87; British sterling silver, 66; and German mark, 67.3 pence.

The great driving force operating in the market for the last few years was clearly indicated by the statement made in the House of Commons on May 12 by the Secretary of State for India, when he said that Indian net imports of silver during the War had amounted to 518,202,000 oz (sufficient to coin about 1,500,000,000 rupees). In addition to this enormous amount of precious metal, net imports of gold totalling £21,400,000 were received during the same period.

On May 12 the forward rate eased to 57¼ pence, while the cash quotation remained unaltered. On the next and succeeding days, supplies were forthcoming on a scale sufficient to meet the demand, and brought about lower rates. It is satisfactory that a substantial business has been done during the week on this market, and it has been easy both to buy and to sell large quantities.

The China exchanges have not moved in anything like the same proportion as the value of silver. The silver quotation on May 15 is equal to 5s. 3 5/16d. per tael (expenses of transmission excluded) as compared with the cabled rate of 5s. 2½d. per tael (a tael is 579.84 grains of silver).

LEAD

Lead is quoted in cents per pound, New York delivery.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Eastern Metal Market

New York, June 4.

There is no pronounced activity in any of the markets; some are strong and some are easy.

Antimony is strong.

Copper has broadened, with prices firm and the tendency upward, following a week of lighter demand.

Lead has become very quiet and prices are easier.

Tin is quiet, with developments of a minor nature.

Zinc is lifeless and prices are nominal.

ANTIMONY

The market is strong with wholesale lots for early delivery quoted at 8.37½ to 8.50c., New York, duty paid.

COPPER

The market is quiet, but there is a steady demand, which has increased somewhat after the subsidence in activity last week. Buying during May was of large proportions—much larger than at any time since the War ended. Some say it is about equal to production, but this is not known. Output is generally conceded to be not over 50% of capacity. Prices are distinctly firm, with some producers well sold for June or June-July delivery. In fact, some of the large interests are only selling for June-July or not for June, and are asking 16.50 to 17c. for electrolytic. There are one or two smaller interests, and speculators who have sold as low as 16.25c.; but the quantity involved has been very small. For August delivery most sellers are averse to committing themselves, but when necessary they demand at least 17 to 17.25c. for electrolytic copper. Most of the recent and present buying is for domestic consumption with very little heard about export business about which there appears to be some mystery, especially as to prices involved. The general tone of the market is strong and firm, with electrolytic copper for early delivery quoted at 16.50 to 16.75c., New York, and Lake at 16.75 to 17c., New York.

IRON AND STEEL

Activity in the steel market continues moderate, but it is of an encouraging nature. The schedule of March 20, made between the steel-makers' committee and the Industrial Board, continues as the market standard, though there are some price irregularities. Export demand grows, and the business is more dependable. There are signs that foreign buyers, who were waiting to get their cue from the attitude of domestic buyers, are now coming forward. Japan is in the market for another lot of 10,000 tons of rails. Early expansion in structural orders is indicated by inquiries.

The blowing out of blast-furnaces continues. The output in May was 2,108,056 tons, or 68,000 tons per day, against 2,478,218 tons in April, or 82,607 tons per day. The May rate was the lowest since March, 1915.

LEAD

The market has become very quiet. As a result of the extensive buying a short time ago, which was of large proportions, consumers are apparently filled up and the activity has subsided. There are a few sellers who are now slightly shading the A. S. & R. price of 5c., St. Louis, or 5.25c., New York. They have done some business at 5.20c., or 4.95c., St. Louis, but it has not been large. Some of this is probably speculative metal bought at lower levels. We quote the market at these lower outside levels.

TIN

During recent weeks the only activity has been in future shipment metal when restrictions are removed—in fact it is only such trading that has been possible in a market still under war rules. But even this has subsided again to small proportions although in the last week there has been a little buying at 51 to 51.50c. for shipment from the Straits. On Monday, George Armsby, chief in charge of tin of the War Trade Board, made public the stocks of allocated metal still on hand on June 1 as 1615 tons. This is a decline of about 50% for May, and is taken to forecast the absorption of all the original 10,000 tons by July 1. There is no definite news as to when the market will again be free. The London market fell on May 23, following the state of the American market, but has turned stronger again since then.

ZINC

Conditions and demand are worse than at any time since the armistice, says one large producer. No betterment is looked for until general conditions in steel and other lines are improved decidedly. Quotations for prime Western are nominal at 6.15c., St. Louis, or 6.50c., New York, for early delivery, with transactions limited to small allotments to cover necessities in isolated cases. For future delivery a premium is asked, but there is but little demand.

ORE

Manganese: Imports in April were 59,470 long tons, a large quantity, bringing the total for the four months to May 1 to 174,791 tons, or 43,698 tons per month. This rate compares with 40,942 tons per month in all of 1918.

Manganese-Iron Alloys: British makers of ferro have met the American product and are offering the alloy at $121, seaboard, as against $125, delivered, for the American alloy. Spiegel is obtainable at $30 to $35, furnace. Demand for both is light.

Molybdenum: This market is dead and prices are nominal at say 80 cents per pound.

Tungsten: Conditions are unchanged and demand is not large. No fair test of the market has been reported. High-grade ores continue nominal at $7 to $10 per unit in 60% concentrates. Ferro-tungsten has not been tested, and no definite quotations are available.

Book Review

Waterproofing Engineering. By Joseph Ross. Pp. 427, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, $5.

As the author points out, the literature on waterproofing processes and practice is remarkable principally because there is so little of it. Not only has little investigation of the subject been done, but many of these who have made such studies have, for commercial reasons, kept the results of their work secret. The chapter-headings are as follows: Need and Function of Waterproofing; Systems of Waterproofing; Impervious Roofing; Waterproofing Expansion-Joints in Masonry; Waterproofing-Materials; Waterproofing Implements and Machinery; Technical and Practical Tests; Specifications; Recipes and Special Formulas; Application; Cost Data. Another chapter contains a number of tables of special use in this class of work. There are appendixes containing a discussion of mechanical analysis of concrete aggregates, concrete in sea-water, the American Society for Testing Materials report on waterproofing, a glossary, and a list of references. The book will be useful to anyone engaged in the erection of buildings or other structures that have to be waterproof, or at least moisture-resistive.

Company Reports

ANACONDA COPPER MINING CO.

Property: Copper and zinc mines at Butte, concentrating, flotation, and leaching plants for copper and zinc at Anaconda; copper smelter, acid, and power-plants at Anaconda; copper smelter and rod-mills, electrolytic copper refinery, zinc refinery, ferro-manganese, and calcium-carbide plants at Great Falls; also coal mines, lumber camps, and railroads, in Montana; also copper mines in Chile, and subsidiary smelting companies in Arizona, Indiana, and Utah.

Operating Officials: At Butte—Charles W. Goodale, chairman of safety-first committee; John Gillie, general manager of mines; Bertram H. Dunshee, assistant; William B. Daly, general superintendent of mines; John O'Neill, assistant; D. A. Welch, purchasing agent.

At Anaconda—Frederick Laist, manager of Washoe Reduction Works; Louis V. Bender, general superintendent; H. S. Ware, assistant; B. S. Morrow, superintendent of concentration; S. S. Rodgers and C. W. Morse, assistants; Pierce Barker, superintendent of blast-furnace department; R. W. Handley, superintendent of zinc concentrator; Wallace N. Tanner, chief mechanical engineer; Charles D. Demond, engineer of tests; L. E. Jones, chief electrical engineer; E. A. Barnard, chief chemist; F. W. C. Whyte, manager of coal mining department; H. A. Gallwey, manager of Butte, Anaconda & Pacific Railway; D. A. Welch, purchasing agent at Butte.

At Great Falls—James O'Grady, manager; Albert E. Wiggin, general superintendent; Milo W. Krejci, assistant; Earl S. Bardwell, metallurgist; Russell B. Caples, superintendent of electrolytic refinery; E. E. Brownson, chief chemist.

Financial Statement: the past four years compare as under:

	1918	1917	1916	1915
Sales of metals.....	$102,586,541	$109,055,593	$96,097,700	$61,473,677
Gross revenue, including metal on hand	147,618,801	156,205,157	148,190,046	87,273,886
Disbursements	122,902,728	118,706,777	91,647,708	67,806,191
Balance	24 716 073	37,498,380	56,542,338	19,467,695
Income from investments	2 867,514	2,749 083	2,350,641	112,922
Interest paid	676 532	526,275	951 144	984 233
Depreciation	6,101,185	5,387,437	7 113,163	1,900,578
Profit	20,802,870	34,333,751	50,828,372	16,695,806
Dividends	17 484,372	19,815,625	17,484,375	9,325 000
Surplus	3 318 498	14,518,126	33,343,997	7,370,806
Profit and loss surplus	66,232,486	62 913,988	48,395,862	15,051,865

Current liabilities total $71,979,453, including $27,865,266 for metals on hand, and liabilities $38,932,231.

Development and Mining: 41.85 miles of development, compared with 38.61 miles in 1917, was done. The shafts of the company were sunk additional depths aggregating 4991 ft. Results were quite satisfactory.

The Bonanza shaft was sunk an additional depth of 512 ft. to the 1000-ft. level. Cross-cuts were driven in both directions from both the 500 and 1000-ft. levels, and while several veins were cut, none of them were of value worthy of note. The shaft on the Orphan Girl claim was sunk to a depth of 525 ft. A cross-cut was driven in a southerly direction to cut the Orphan Girl vein. The vein was found, but was practically of no value. A north cross-cut was started to cut the veins known to apex on the Orphan Boy and Anglo-Saxon claims.

At the Never Sweat mine, one Ingersoll-Rogler compressor, having a capacity of 7500 cu. ft. of air per minute, was installed. At the Mountain Con., one Nordberg first-motion air-hoist was put in. There was erected at the Parnell shaft a plant for making concrete slabs for shaft-lining. At the Nettie mine, a new office and change-house were completed. At the Rarus shaft, installation was completed of a new 34 by 72-in. Nordberg hoisting engine, operated by air, together with new head-frame and complete shaft-collar equipment. There were erected five Sirocco double and single inlet fans, having a capacity of 228,000 cu. ft. of air per minute. Experiments were carried on at the Parnell shaft endeavoring to improve the passage of the air-currents through the shaft by removing the resistance offered by exposed timbers. Concrete slabs were put in place between the timbers, and the results obtained were so satisfactory that it is the intention to equip all shafts in like manner. Several of the mines in which the new system of ventilation has been completed show markedly the good results obtained.

All of the stations and 3399 ft. of the High Ore shaft were fireproofed during the year. The Belmont shaft was fireproofed from surface to the 2800-ft. level, including all stations. At the Rarus shaft, 1609 ft. was re-timbered and fireproofing placed upon the timbers from the surface to the 2100-ft. level, including all stations.

MAP OF WESTERN STATES SHOWING CENTRES OF OPERATIONS BY THE ANACONDA AND SUBSIDIARIES.

The mines of the company produced during the year 4,918,468 tons of ore, and 6553 tons of copper precipitates from water, a total of 4,925,021 tons.

Production: smelter output (including that from purchased ores) for a series of years follows:

	Copper, lb.	Silver, oz	Gold, oz
1918	293,603 726	10,967,905	64,317
1917	253,508,332	9,031 025	58,545
1916	331,893,273	11,837,769	92,090
1915	254,311,574	9,005,617	108,702
1914	223 720,202	8,314,116	96,651
1913	270,301,644	10,321,296	64,808
1912	294,474 161	11,014,737	61,314
1911	259 407 092	9 731,561	48,950
1910	266,608,461	9,531,888	57,260

The copper reduction works treated for all companies during the year 4,959,580 tons of ore and other cupriferous material at Anaconda, and 57,000 tons of ore and other cupriferous material at Great Falls. Of this amount, 4,350,446 tons of ore was produced by company mines, 618,256 tons of ore was either purchased from or treated for other companies, and 47,878 tons of precipitates and cleanings from the old works at Anaconda and Butte were treated

At Anaconda there were produced 279,030,318 lb. of fine copper, 10,001,604 oz. of silver, and 59,403 oz. of gold. At Great Falls there were produced 14,573,408 lb. of fine copper, 966,300 oz. of silver, and 4914 oz. of gold. This makes a total of 293,603,726 lb. of fine copper, 10,967,905 oz. of silver, and 64,317 oz. of gold. Of the total production at these plants, 272,923,031 lb. of fine copper, 10,076,747 oz. of silver, and 64,317 oz. of gold were produced for the company.

The electrolytic copper refinery at Great Falls produced 191,404,125 lb. of cathodes, 189,067,167 lb. of which was melted into shapes at Great Falls.

The copper leaching-plant at Anaconda treated 500,688 tons of tailing and 64,978 tons of copper ore, from which was produced 6662 tons of cement copper.

The zinc plants at Anaconda and Great Falls treated 393,193 tons of ore and other zinciferous material, of which amount 255,057 tons of ore was produced by mines of the company, and 138,136 tons of ore and concentrates were purchased from other companies. At Great Falls there was produced 72,131,238 lb. of electrolytic zinc.

Reduction Works: The electrolytic zinc plant at Great Falls operated continuously with excellent results, as every effort was made to secure as great an output as possible in order to meet the requirements of the Government, as the zinc produced, on account of its purity, was used largely in munition work.

The rod and wire mill was completed during the summer, and the rod mill was put in operation on June 9, and both were in continuous operation during the latter part of the year.

As a result of experience gained in operating the various departments of the zinc plants of the company, it was found that by the expenditure of a proportionately small sum of money, the output of the electrolytic zinc plant at Great Falls could be increased from 100 to 150 tons per day, making it possible to secure a more complete utilization of all equipment at Anaconda and Great Falls, and also reduce the cost of production; accordingly, necessary construction was begun, equipment orders placed, and at the close of the year the increase in the plant had been almost completed.

At the solicitation of the United States government, five electric ferro-manganese furnaces were built at Great Falls, one of which was started in September, and two more went into commission in October and November. The furnaces had a capacity for treating 250 tons of manganese ore per day, and up to November 11 had produced upward of 1000 tons of ferro-manganese, made from ores purchased from Butte Copper & Zinc Co. As the demand for ferro-manganese ceased the furnaces were shut-down.

The mines at Diamondville, Wyoming, produced 625,600 tons of coal. Of this, 398,857 tons was shipped to other departments of the company, 180,409 tons was sold, and 46,334 tons was used at the coal mines. The mines at Washoe, Montana, produced 147,774 tons of coal; 72,513 tons was shipped to other departments, 65,258 tons was sold, and 10,002 tons was used at the coal mines. The mine at Sand Coulee, Montana, produced 292,366 tons of coal; 160,642 tons was shipped to other departments, 131,470 tons was sold, and 254 tons was used at the coal mines.

The sawmills at Hamilton, Hope, Bonner, and St. Regis cut 82,950,859 ft. of lumber, and purchased 41,219,939 ft.; of which 72,162,891 ft. was shipped to the mines, 35,765,541 ft. was sold, 1,415,915 ft. was used at the mills for repairs and construction, and 2,208,966 ft. was supplied to the factory for manufacturing; or a total disposition of 111,553,313 ft., increasing the stock of finished lumber on hand by 12,617,485 ft., leaving a balance on hand December 31, 1918, of 54,027,560 feet.

The subsidiary departments of the company realized a profit from the year's business of $354,187.

The Butte, Anaconda & Pacific Railway transported 5,630,451 tons of freight and ore, and 245,682 passengers. The gross earnings were $2,095,713; rental and miscellaneous receipts, $26,893; operating expenses, $1,535,724; taxes, interest, and rental of leased lines, $213,960; net income, $372,922.

The International Smelting Co. at Tooele, Utah, treated 262,772 tons of copper and 297,847 tons of lead ore, from which there were produced 21,821,657 lb. of fine copper, 62,034,920 lb. of fine lead, 5,827,134 oz. of silver, and 36,317 oz. of gold.

At the Andes Copper Mining Co., Chile, South America, additional churn-drilling was done, aggregating 11,800 ft., by which approximately 5,000,000 tons of ore was added to the reserves. Drifts and raises were driven totaling 2990 ft. It was decided to place the living quarters of the employees at the millsite, and at that point a townsite has been established. It is the intention of the company to make it as attractive as possible for the officials and other employees. One hundred and eighty-four houses are being constructed, varying from 30 to 100% toward completion. The grading of the railroad was completed to the millsite. Thirty-nine miles of track was laid to the west portal of tunnel No. 4, eight miles distant from the millsite.

THARSIS SULPHUR & COPPER CO., LIMITED

Property: mines and works in Spain, and works in Great Britain.

Financial Statement: profit for the year ended December 31, 1918, was £243,216 ($1,178,500), but after deducting taxes, general expenses, and depreciation, this was reduced to £154,035 ($746,900). The gross profit in 52 years totaled £14,891,985 ($72,226,000), of which £11,451,574 ($55,542,000) was net.

Dividends: £125,000 ($606,000) was paid in 1918, making £10,758,432 ($52,176,000) since 1866. Last year's rate was 10% on capital, and the total 948½%.

Production: the Calañas mine produced 328,601 tons of ore, a decrease of 78,618 tons. The yield of refined copper was 3246 long tons, compared with 4066, 3712, and 3970 tons in the previous three years.

At the Tharsis mine 215,000 cubic meters of overburden was removed. A large quantity of pyrite is now ready.

NORTH BROKEN HILL LIMITED

Property: mine and mill at Broken Hill, New South Wales, Australia.

Operating Official: G. Weir, general manager.

Financial Statement: during the half-year ended December 31, 1918, sales of concentrate and tailing realized £306,658 ($1,460,000). The profit was £176,609 ($840,000). The surplus of assets is £615,350 ($2,950,000).

Dividends: No. 49 and 50 absorbed £120,000 ($576,000).

Development: the main shaft was completed to a depth of 1778 ft. A ventilating shaft is being sunk to 800 ft. Total new work amounted to 861 ft. The quantity of ore available above the 1400-ft. level is calculated at 2,600,000 tons. Mining cost 21/8 ($5.20) per ton.

Production: the mill treated 74,385 tons, averaging 15.7% lead, 8.5 oz. silver, and 12.8% zinc. The recovery in concentrate was 82.5% of the lead and 62.7% of the silver, the 14,948 tons of concentrate assaying 64.6% lead, 26.6 oz. silver, and 7.4% zinc. The zincy tailing—40,683 tons carrying 15.3% zinc—was sent to the Amalgamated Zinc (De Bavay's) flotation plant for further treatment. Milling cost $2.08 per ton.

EDITORIAL

SILVER absorbed by India, that is, net imports, during the War, amounted to 516,202,000 ounces; and gold 5,030,000 ounces. The world's production during this period was 701,000,000 ounces of silver and 83,210,000 ounces of gold. Some interesting notes on silver were published on our metal page last week. The term 'Chinese tael' is frequently used in connection with silver movements, prices, and exchange in the Orient, and it might be explained here that the tael is not a coin but a weight equal to 579.84 grains.

COPPER is gaining in strength. The quotations of shares of the companies producing the metal are higher than at any time since the armistice was signed, although the price of the metal has declined six cents per pound during the intervening seven months. The buoyancy of the share-market reflects the general optimism of the country and of the mining public. France has lifted the embargo on imports of copper; other European countries, including those with whom peace is about to be concluded, will shortly become buyers. In May the sales of copper were larger than had been expected; they were even in excess of production during the month.

WE in this country hardly realize how we have escaped most of the effects of the War. We are optimistic and cheerful; in England they are anxious and gloomy. A metallurgist well known to our readers writes: "It all seems so strange. I cannot believe that people are five years older, that patents have five years less to run, or that generally five years have been taken out of my professional life." Another, a veteran formerly conspicuous in copper smelting, writes: "The whole world is in trouble. England particularly has labor pains, and what the issue will be, I don't know. It is at present full of gloomy forebodings."

AMONG methods of education we commend to the attention of our readers the lectures for shift-bosses organized by the Phelps Dodge Corporation at Bisbee. The Copper Queen branch of this public-spirited company is conducting a course of 43 lectures for shift-bosses. These lectures or talks are delivered for the most part by foremen, superintendents, and engineers on the company's staff. We note in addition that the manager, Mr. G. H. Dowell, will talk on 'Company Policies', Mr. R. B. von Kleinsmid, the President of the University of Arizona, will give a discourse on 'The Psychology of Handling Men', Mr. J. B. Tenney, the Chief Geologist, will explain 'The General Geology of the Warren District', and Mr. Gerald Sherman, the Consulting Engineer, will describe 'Caving Methods'. The list of subjects is most attractive, and we feel sure that the well-meant effort to give technical instruction to that worthy person the shift-boss will be successful. After all, there is the manager, and his assistant, and the engineer, and the geologist, but the real work of the mine is in the hands of the shift-boss. He is worthy of the most kindly and respectful consideration.

AT a recent meeting of the North Idaho Chamber of Commerce, while in session at Moscow, an address was delivered by Mr. J. B. Eldridge, vice-president of the Idaho Mining Association, and in the course of that address he made a plea for the building of roads to aid the development of the mineral resources of the State. We sympathize with that plea. As Mr. Eldridge said, barely one-tenth of Idaho's mineral area is open to profitable mining operations on account of the lack of transportation. In this matter we commend the State legislature to study the policy adopted by British Columbia, in which province the government builds a considerable mileage of roads every year and thereby stimulates the development of the country.

THE Canadian government has appointed a commission to inquire into the feasibility of introducing herds of reindeer and musk-oxen into parts of Arctic and near-Arctic Canada with a view to their forming a source of meat for the inhabitants of these remote regions. It would also be well to take strong measures for the protection of the few remaining musk-oxen and to pass a law forbidding the shooting of the female caribou. The natives in the far North are acquiring rifles and they are slaughtering these wild animals with great ease as compared to the time when they had only their bows and arrows. We make mention of this matter in the interest of the prospector, to whom the larger four-footed game affords a necessary source of food.

SUPPRESSION or curtailment of the foreign press in the United States is being advocated in Congress. This is due to the fact, it is reported, that evidence has accumulated to prove that the foreign press, in its effort to strengthen itself with the elements to which it appeals, has preached treason against our Government; it has tried to maintain the use of European languages and customs among our alien population and has endeavored to create a divided allegiance in the minds of their children. Much of this we believe to be true, but the total suppression of all papers and magazines not printed in the English language would be a step so illiberal as to warrant protest from those whose better judgment has not been swamped by violent prejudice. It seems to us that all that is desirable in the way of reform and discipline in this direction can be accomplished by passing a law to compel every foreign-language paper to print an English translation of its foreign text in the next column. This would serve, in the first place, as a tax on publication, increasing the cost sufficiently to diminish the number of foreign papers circulated; in the second place, such a regulation would, by furnishing an immediate English translation, help to teach our language to the immigrant and his children, thereby hastening the process of kindly assimilation.

IT is an interesting coincidence that at the time when the latest pronouncement of the U. S. Supreme Court in the flotation litigation is made known, it is announced that Mr. James M. Hyde has been appointed Professor of Metallurgy in Stanford University. We are glad of it, for Mr. Hyde has a logical mind and unusual power of exposition. He ought to prove an effective teacher, in co-operation with Mr. Theodore J. Hoover, who has been appointed Dean of the Mining Department at Stanford. Mr. Hoover, as our readers will recall, used to be metallurgical engineer to the Minerals Separation company and he wrote the first book on the flotation process. His world-wide experience of mining ought to stand him in good stead and his proved ability in the art of exposition likewise should serve him well as a professor. In early youth he had some training as a journalist on the Oakland 'Tribune' and since then his contributions to the technical press have enabled him further to develop his powers of expression. Here we may advert to the fact that Mr. Hugh F. Picard, the junior member of the firm of Sulman & Picard, the metallurgists to Minerals Separation and the recognized inventors of the basic patents, has been elected president of the Institution of Mining and Metallurgy in London. Mr. Picard is a brilliant technician and possessed of so many engaging qualities that his election has been received with pleasure both in London and in this country. We expect to publish his presidential address in a forthcoming issue of this paper.

IN these days of multitudinous newspapers and magazines it is remarkable how little really trustworthy information is available. For instance, note the extraordinary diversity of opinion concerning industrial conditions in the countries of Europe. The difficulty is due largely to personal bias and individual prejudice. A clever man like Mr. Vanderlip delivers a long and deeply interesting speech immediately after his arrival from Europe and one would suppose that his statements could be accepted unreservedly. Nothing of the kind. He said three or four things that any well-informed man knows to be incorrect, mainly by reason of exaggeration incidental to an effort to emphasize. The general effect of his speech was, we thing, misleading. Every great war is followed by a period of disorganization, poverty, and political unrest, but history tells us that in most cases the recovery and rehabilitation have been much more rapid than seemed possible while under the effects of the reaction inevitable from such a calamity. Mr. Hoover's speech, on the same topic, seems to us to be more sagacious and better balanced. His views concerning the feeding of the European peoples are nothing like so gloomy as Mr. Vanderlip's, but he recognizes the urgent necessity for allowing the European countries, especially Germany, to obtain the raw material that is essential to the life of manufacture. He makes the wise suggestion that we stop the lending of money by our Government to the European countries, because this invites extravagance, not thrift, but that the lending of capital be done by private persons and corporations to governments and individuals in Europe, in order to assist the restoration of industry and the re-establishment of a normal market for our products.

UNDER 'Discussion' we publish a letter from Mr. William Forstner, who is honorably known as a specialist in the mining of quicksilver. It is on this subject that he writes, making a plea for some measure of protection to the industry. As some of our readers are aware Mr. F. L. Ransome, of the U. S. Geological Survey, in a recent Bulletin, forecasted the decline of quicksilver mining in this country, because, among other reasons, it cannot compete with imports of cheaper metal from Spain. He expressed himself in opposition to the idea of stimulating the American production by tariff protection. As the industry is mainly centralized in California this official expression of opinion annoyed many of our friends in San Francisco, and one of them, Mr. Murray Innes, indited a vigorous protest to the Vice-Chairman of the Tariff Commission, taking strong exception to "this destructive attitude at Washington," which appeared to play into the hands of the Rothschilds. Mr. Fletcher Hamilton, the State Mineralogist of California, likewise made a protest, in the form of a letter to the Secretary of the Interior, in which he ascribed the depression in our domestic quicksilver industry to the "increasing importation of Mexican quicksilver, which is produced with the aid of peon labor." Now comes our friend Mr. Forstner with a temperate plea, to which our readers will, we think, give sympathetic attention. He says, most sensibly, that if the domestic producers of quicksilver desire to safeguard their industry they must co-operate with others similarly situated; it is useless to play a lone hand in any effort to influence legislative action. For ourselves, we think it highly desirable that this country should be independent of foreign supplies of metals and minerals if such supplies can be made available at home; the idea of being industrially self-contained is not one to be set aside lightly. Moreover, in respect of tin, antimony, chrome, manganese, tungsten, and quicksilver, we believe that if the mining of them is stimulated by some measure of protection, whether by an import-duty or a bonus, there is a chance of deposits being found and developed of such richness and size that an adequate supply will be forthcoming at a cost rendering the domestic industry strong enough to withstand foreign competition.

The Flotation Decision

On another page we publish the full text of the U. S. Supreme Court's opinion in the case of Minerals Separation, Limited, v. Butte & Superior Mining Company. The issue was the scope of patent No. 835,120, the validity of which had been established previously by the Court's decision in the Hyde case. In that decision the Court had limited the patent to a "critical proportion" of oil, "amounting to a fraction of 1% on the ore," but had not itself defined the fraction except by referring to the testimony in the case and to the patent itself. In consequence, the defendant company took the position that the critical proportion so described was one-half of 1% or less. This was tested by the starting of a new suit by the Minerals Separation company as soon as the Hyde case was concluded, this time against the company by whom Mr. J. M. Hyde was employed professionally and by whom he had been backed in his litigation with the Minerals Separation company. The District Court of Montana refused to accept "half of 1%" as a definition of the Supreme Court's "a fraction of 1%," but the Ninth Circuit Court of Appeals, sitting in San Francisco, decided in favor of that interpretation; whereupon the issue was referred again, on writ of certiorari, to the Supreme Court of the United States. This Court now holds that the appellate court, by limiting the scope of the patent to half of 1%, fell into error in interpreting the final decision in the Hyde case, and also holds that "the patent extends to and covers the use, in the process, of oils of the patent in amounts equal to *any* fraction of 1% on the ore." The italics are ours. The Supreme Court says that the patentees are entitled to claim "a reasonable degree of variation," in the proportion of oil used in the process, "within the terms of the claims" of the patent, and that "the restriction of the amount to a fraction of 1% was reasonable and lawful." Further, as to any conflict between two expressions used in the testimony and in the patent, "the language of the claims must rule in determining the rights of the patentees." Thus the importance of the admission made by Mr. Kenyon to Mr. Justice McReynolds, as quoted in the defendant's oral argument, which was printed in our issue of May 31, is lessened, although Mr. Justice Clarke, who delivered the opinion of the Supreme Court, says that it was "impressive and significant." Mr. Kenyon's admission and the evidence in the record have impelled the court of last resort to decide that the metallurgic results under the patent "could not be obtained with more than a fraction of 1%" of oil, therefore the appellate court's decree is sustained in so far as it held that the use of more than 1% does "not constitute infringement." As to the use of mineral oil, the Court concludes that better results probably would have been obtained by the use of less than 1% of pine oil alone, but since the mineral-oil has a "preferential affinity for metalliferous matter," as specified in the patent, the use of it is not an infringement if the aggregate amount of all oils is in excess of 1%. "The patent is on the process; it is not and cannot be on the result," says the Court. This is important; it may serve as a new point of departure. In short, the patent rights of the Minerals Separation company are upheld in respect of the use of any proportion of any oil up to 1%, but not beyond that point. This, even in the present state of the art, does not give them a monopoly of flotation, but it is a blow to the economical use of the process because, although it can be conducted successfully with more than 20 pounds of oil per ton of ore, it is a fact that the larger proportion of oil is a nuisance in the mill and entails an extra cost of about one cent per pound of additional oil. Nevertheless, even the extra cost and trouble will be preferred by the managements of some of the mining companies to paying a royalty to the Minerals Separation company and becoming subject to its inquisitorial methods. We are informed, for example, that the Butte & Superior company will continue to use more than 1% of oil, preferring to meet the additional cost of the extra proportion of cheap oils than to take a license from the Minerals Separation company and pay a royalty on its 'below 1%' process. It is also announced that the defendant in the recent suit is prepared to continue the use of the permissible proportion of oil until the expiration of the Minerals Separation patent in November 1923, "after which time," it is stated, "the use of the process with any quantity of oil will be free and open to the public." There remains also a reasonable expectation that before the expiration of patent 835,120, four years hence, a more economical and more efficient process of concentration will be devised, for a number of new ideas are in course of trial. Meanwhile the Minerals Separation people, presumably, will collect heavy damages for past infringements, not only from the Butte & Superior company but from the big copper-mining companies that have been using the same methods of flotation during the past three or four years. Whether they also will elect to use the 'over 1%' proportion of oil, rather than pay toll to the Minerals Separation company, we do not know, but as some of them are under the same direction as the Butte & Superior company, such a decision seems probable. What attitude the patent-owning company will assume toward the industry in the future is another matter of conjecture; in the past its tactics have been needlessly offensive and we have not hesitated to condemn them. Whether the legal weapon put into the hands of the Minerals Separation people will be used gently or fiercely, we cannot tell, but we venture to suggest that as the opinion of the Supreme Court affords a means of escape from their clutches, by the use of 20 pounds or more of oil, they will be wise in so arranging their scale of royalties that it will become advantageous to take a license from them, and besides abating their demand for excessive royalties they will show wisdom in adopting a more conciliatory policy in other respects. The entire controversy proves once again how undesirable it is to leave the decision of technical and scientific questions to courts composed of men without a special training for the understanding of such questions. With all respect to the Supreme Court, we venture to say that no unbiased metallurgist familiar with the operation of the flotation process will accept, even for a moment, the suggestion that the process that is successful when using half of 1% of oil is at all different from the process that works successfully when using 1% or 1.25% of oil. It is essentially the same process, and if the Minerals Separation people did anything for the advancement of the art it was in showing that so small a quantity as three or four pounds—0.15 or 0.2%—of oil sufficed with most ores to produce an effective metallurgic result; in other words, what they did was to show how oil could be economized and the process simplified thereby, for the more oil the more messy the operations. An issue involving an enormous amount of money and vital to the interests of a basic industry has gone for adjudication to jurists devoid of the special education required for the purpose, and without the time needed for the proper preparation of the requisite understanding of the technical problems involved. It is not the least remarkable feature of the latest opinion that it should have been delivered so soon, for the case was heard before the Court so recently as last March, less than three months ago. Of the eight decisions in the three flotation lawsuits (Hyde, Miami, and Butte & Superior) by the various courts, it can be said that they are as contradictory as they are diverse, and that each one has been vitiated by the incompleteness of the evidence in the record and by the lack, on the part of the courts, of the intimate knowledge of the subject that is necessary for a real understanding of it. We here repeat, what we have intimated more than once, that the story of the invention of the process as told in the courts is unconvincing and the explanations of its physical principles absurdly variable and contradictory. The essential features of the process as far as disclosed in the patent were known at Broken Hill some time before the supposed discovery in March 1905, and if the metallurgists at work in the Central mill at Broken Hill in 1903 and 1904 could have been subpoenaed before the American courts, it would have been possible, we believe, to throw a different light on the claims of the supposed inventors. Other patents remain and further litigation is assured, for some of the patents antedating No. 835,120 are held in this country by opponents of the Minerals Separation company. Therefore we deprecate any feeling of undue discouragement at this time and urge the leaders of the mining industry in the United States to consult with one another for the purpose of defensive co-operation immediately, since the District Court of Montana must forthwith amend its decision in conformity with the decree handed down by the Supreme Court.

Gold and Silver

The embargo on the exportation of gold and the control over foreign exchange were lifted by the Federal Reserve Board on June 9, thereby removing the prohibitions that went into effect on September 10, 1917. During the interval only small quantities of gold were allowed to go out of the country and only by special permission of the Federal Reserve Board, through whom the national control of gold is exercised. However, exportation of the standard metal is still denied to Russia and to the Enemy countries, although this remaining check may be removed as soon as peace has become a legal fact. Applications for both gold and silver exports must, however, continue to be made to the Federal Reserve Board, until such time as the President shall, by proclamation, formally bring to an end the present control. Now that the ban on the exportation of both the money metals has been lifted the restoration of foreign trade should be accelerated, without cutting into our supply of gold, because rates of exchange are generally below the point at which exportation is feasible; indeed, it is noteworthy that the first part of a shipment of $50,000,000 in gold has recently reached New York from Canada. We welcome the free movement of gold and silver as a means of restoring the precious metals to their normal function in commerce and of ascertaining the real status of the enormous volume of paper money created in the belligerent countries during the War. Meanwhile the resumption of silver exportation to the Orient has given that metal a market-value not far from its coinage-value and promises to maintain the price at the current high level, much to the advantage of the miner. Silver stands today at nearly double the average quotation during 1914. Production has declined all over the world, the total of 177,453,000 ounces in 1918 being 48,500,000 ounces less than in 1911. Of the 67,879,200 ounces of silver produced in the United States last year, 72,572,506 ounces came through the American Smelting & Refining Company and 10,700,000 ounces represented a by-product from the copper-mining operations of the Anaconda. In the same year the United States Smelting, Refining & Mining Company produced 15,337,465 ounces of silver, most of it however coming from its mines at Pachuca, Mexico. Of the total world's stock of gold the United States now holds one-third, as against one-quarter before the War. Of the total stock of gold money existing at the end of 1913, 63% was in government banks or treasuries and 37% in the hands of private banks and the public. A year ago the proportions had changed to 85% and 15% respectively. This is one of the momentous consequences of the War, which had the effect of withdrawing gold from circulation and of concentrating it in the hands of governmental institutions. Concurrently the production of gold has declined, in part owing to the world-wide inflation of labor, which has greatly increased the cost of producing the metal and discouraged the search for new ore deposits. It remains to be seen what will be the after-war effect on our monetary standard.

DISCUSSION

The Leaching of Flotation Concentrate

The Editor:

Sir—In regard to the interesting article by Percy R. Middleton in your issue of June 7 on the leaching of flotation concentrate, I think it would be instructive if he would give us a little more detail as to his proposed methods and flow-sheet.

1. I notice that in his tests at the Edwards metallurgical works he treated his roasted product by percolation but in his estimate for a 100-ton plant he evidently contemplates agitation treatment by means of Dorr counter-current thickeners; the question then arises, why does he abandon the idea of percolation, which presumably worked satisfactorily in his large-scale test? If it be possible to use percolation that method would seem much simpler than agitation and decantation.

2. He apparently proposes to use a sulphuric acid solution to dissolve the 5 or 10% of copper that has escaped sulphatization but he does not allow for any dissolving-tank or tanks preliminary to the Dorr counter-current system. Am I right in supposing that he intends to add his acid to the pulp as it flows into the first thickener? This would seem to involve a misplacement of acid, since the overflow of that thickener would normally go directly to precipitation; moreover, in order to obtain the maximum washing efficiency from the Dorr method dissolving should be as nearly as possible complete before washing begins.

3. I fail to grasp his meaning when he states that "it is an open question whether the advantage of using one solution for the recovery of both gold and silver would offset the danger of incomplete washing in a large plant." Is he referring to washing of the pulp between the copper extraction and the cyanide treatment for gold and silver, or to the final washing out of the gold and silver? If the latter, why worry, since this operation is being performed successfully every day in large as well as small plants?

4. He appears to assume that the silver could be extracted by cyanidation after roasting, without previous chlorination, but this is contrary to the usual experience. As a general rule the roasting of an ore which when raw is perfectly amenable to cyanidation renders it so refractory that only from 20 to 30% can be extracted by that method.

5. In his proposed flow-sheet he does not give any indication of the method he intends to adopt for chlorinating the pulp after it leaves the last washing-thickener of the copper-dissolving process.

6. He states that "laboratory experiments show that after chlorination the silver is in a condition suitable for extraction by either hyposulphite or brine." It would have been interesting if he had given some more data on this point, as, for instance, the methods used, and the extraction obtained, with original and residue assays.

7. In his profit-and-loss tables, comparing the wet treatment with smelting, he assumes an extraction of 90% of the gold and nearly 89% of the silver; has he any working data as a foundation for this estimate? And are the figures meant to apply to chlorination followed by water and 'hypo' treatment successively or to direct cyanidation?

I think that if he would make these various points clear the value of his article would be greatly enhanced.

E. M. Hamilton.

San Francisco, June 9.

Protecting the Quicksilver Industry

The Editor:

Sir—The second annual report of the U. S. Tariff Commission contains a chapter discussing in detail the quicksilver industry. The conclusions of the Tariff Commission regarding the protection to be afforded to the quicksilver industry in the United States in the future, are as follows:

"In the case of quicksilver the question can be squarely raised as to whether the production of this metal can be considered an effective American industry, in as much as abundant cheaper sources of supply exist elsewhere. It is particularly an example of an industry whose products are placed on the market at high cost because of the relatively inferior natural resources of this country in the raw material. Quicksilver is an essential metal, however, of vital necessity in the conduct of war and widely used in the industries. It is stated that American resources, although low-grade, can furnish an adequate supply for many years if a stable and sufficient price be guaranteed. Without tariff protection the United States will be dependent in large part on outside sources for a vital commodity, and a grave question of national expediency is involved."

From the above quotation it appears that the Tariff Commission considers the importance of quicksilver as a war material the main reason for advocating the protection of the quicksilver industry in the United States. Whether, in view of the very slight chance of this country again confronting war conditions within a large lapse of years, the importance of quicksilver as a war material would be a sufficient reason for Congress to protect this industry by a sufficiently high import-tax, is in my opinion very doubtful. The more so, as another Government department, the U. S. Geological Survey, is opposed* to any protection of the quicksilver industry, which would be sufficiently high to keep the price of the metal at a point reasonably remunerative to the producer.

There are no data at hand for the world production of quicksilver later than the year 1913; taking the years 1910 to 1913, the average contribution of the various producing countries was as follows:

	%		%
United States	18.7	Spain	34.1
Austria	19.7	Mexico, etc.	4.2
Italy	23.3		

The output of Spain and Italy being under the control of the Rothschilds, these control 57.5% of the world's output, leaving out of consideration the Austrian output, which it is claimed will also fall under their control. The contract between the Spanish government and the Rothschilds stipulates that the latter shall market the quicksilver on the London market for £7, or higher, and considering the cost of production in Spain and Italy, the Rothschilds can place the quicksilver on the market at that price, if they so desire, without incurring any loss. At the present costs for labor and materials no quicksilver can be produced in the United States at a figure enabling competition with such a price, and consequently, unless protected by a sufficiently high import-duty, the quicksilver industry in the United States finds itself entirely at the mercy of the Rothschilds in London, who, if they so desire, can close every quicksilver mine in the United States. It is useless to argue that such a proceeding is unlikely. Suppose even that the Austrian quicksilver production does not fall into their hands, as is generally believed will be the case, even then the Rothschilds after killing production in the United States, would control, taking the above given average for 1910 to 1913, a little over 70% of the world's production, and after having extinguished the quicksilver industry in the United States, they can put up the price at whatever figure they choose.

Leaving the war-time figures out of consideration, we find that for the period 1910 to 1915, both inclusive, the average yearly domestic production was 20,786 flasks, and the consumption 23,280 flasks; showing that prior to the War production was lower than consumption. Estimating the average cost of production during that period at $50 per flask, the total average yearly disbursement by the industry was $1,040,000.

While a tariff, high enough to prevent the extinction of the quicksilver industry in the United States, may for a time raise the cost of the metal to the consumer, it will, on the other hand, be a protection against extravagantly high prices in the future.

If the quicksilver producers in the United States, however, intend to protect the life of their industry they must come together, organize, and interest the other mineral producers in their case, so that they may be able to submit their contention to the powers that be, fortified by the support of interests large enough to command earnest consideration. They must realize that individual attempts to influence legislative action are of no avail, and only thoroughly organized efforts can possibly bring about the desired results.

WILLIAM FORSTNER.

The Status of Gold

The Editor:

Sir—Referring to Mr. Robbins' letter on this subject in your issue of May 17, permit me to offer the following quotations from his letter together with some comments thereon, which seem to me to be pertinent.

He says "No proof is presented by Mr. Benedict that the financial world reached finality in its conceptions of 1812."

The words of that paragraph seem to be somewhat involved, but if it is intended to mean that the adoption of the gold standard by Great Britain in 1812 (actually in 1816, as will be shown below) will forever prevent the adoption of any other standard by the financial world, I confess I have no proof to the contrary, nor do I feel called upon to present any, because there is nothing in my letter or in any of my previous contributions, that I am aware of, that even hinted at such an idea. But, in this connection let me quote from one of those 800 books on economics, for which he seems to have so little respect.

In 1774 "Parliament passed a law providing that the silver coins should not be legal tender for more than £25 in one payment, except by weight at the rate of 5s.2d. per ounce. It was enacted that gold coins deficient in weight should be called in and re-coined and thereafter such coins under a certain weight should not be legal tender at all. Light-weight coins were made unavailable in payments. After the experience of a quarter of a century Parliament and the people were convinced that the act of 1774, although adopted as a temporary measure, ought to be made permanent; accordingly it was made so in 1799. Yet it was not until 1816 that the true philosophy of the step was well enough understood to secure its enactment into a settled law."

In substance, that enactment required that 20 lb. troy of standard gold (eleven-twelfths fine) should be coined into 934½ parts or pieces each of which is called a sovereign or pound sterling. But whether that law will remain forever immutable is not for me to predict, as I am endeavoring only to point out a few well-known economic facts which have been "digested and absorbed" from standard works on the science of exchange, including a few of those 800 books.

Again, "Mr. Benedict is not quite clear in his argument that it is not the Government stamp which fixes the value of the coins."

Perhaps you are partly at fault for that, Mr. Editor, for you deleted the two little cubes whose sizes I had calculated so carefully and upon which so much of my argument was based. However, if Mr. Robbins will take the trouble to sketch two cubes of the sizes named in the text and then re-read the argument with the sketches before him it may seem clearer to him. At any rate the combination of the two cubes and the argument, as stated, thoroughly convinced my doubting friend and has since convinced others. Perhaps it might be added that it is perfectly well known to those who have mastered this branch of the science of exchange that it is the quantity of pure gold it contains and not the Government stamp that gives a gold coin its exchange-value or purchasing power.

Again, "In British consols I find Mr. McPherson's 'twin-coin' idea exemplified. Great Britain issued her gold sovereign of a legal weight and fineness and then, doing exactly what Mr. McPherson suggests, she printed £100 on pieces of paper and issued these as running mates for the gold coins. Neither the gold coins nor the pieces of paper are redeemable; they are both money (?), the only difference being that the consol bears interest." Also, in his letter in your issue of March 22, he says, "In 1812 Great Britain needed money for settling war bills and she set about raising these funds by issuing Consols or government bonds. Her proposition was this: To everyone who would give (lend?) her £100 in gold she would give a paper stamped £100."

With Mr. McPherson's permission, permit me to say that, after describing his combination of a $20 gold-piece having a disc of brass on which was stamped "20 dollars" coupled to it, he said, in continuation, "This gold-brass twin coin illustration is given to demonstrate more clearly the fact that one-half the coin is real money and the other half symbol money."

In the name of political economy, how in the world can Mr. Robbins reason out that a consol consists of one-half real money (gold) and the other half symbol money and how are the two coupled together in such a consol? It seems pertinent to add just here that Uncle Sam has just been borrowing the equivalent of gold from his nephews and nieces with which to pay his war-bills, issuing in exchange for such equivalent of gold certain obligations in the form of pieces of paper with various amounts of money printed on them. Some day these various kinds of obligations may be merged into 'American consols', but neither now nor then will they consist of one-half gold (real money) and one-half symbol money. Mr. Robbins did not seem to catch this point of Mr. McPherson's argument, that it is the quantity of gold it contains and not the Government stamp that gives exchange-value to a gold coin.

Again, "Mr. McPherson says further: 'If any nation or group of nations can double the figure on the face of a gold coin . . . that nation can easily treble it or . . . multiply it by tens or hundreds. There is, however, one obstacle always in the way of this and that is the intrinsic and social value of the metal itself'. Just what is meant by "the intrinsic and social value" is not clear, but the facts are that there is no obstacle in the way of any nation doubling the figure on the face of a gold coin."

On the contrary, "the intrinsic and social value" is perfectly clear to anyone who comprehends what constitutes real money. (It was for the purpose of enabling Mr. Robbins to acquire this knowledge that I, in what was intended to be a kind and friendly way, offered to him the hospitality of a certain club, truly hoping he might visit this city in the near future and that I could meet him. I regret very much that my meaning should have been misinterpreted.)

To continue, there is, also, the obstacle of 'common honesty' in the way of doubling the figure on a gold coin, if such coin with the figure so doubled is to be made legal tender in payment for debts incurred before such change took place. It would be legalized robbery, pure and simple; excepting in cases of indebtedness where the contract specifically required the payment of a certain number of dollars in gold coin of the present weight and standard of fineness; which means that a certain weight of gold must be paid over in final settlement of the agreement. For example, $1000 in gold coin of the present weight and standard of fineness is 1000 times 25.8 grains, or 25,800 gr. of standard gold, equivalent to one hundred $10 gold-pieces fresh from the Mint. Mr. Robbins seems to think that if "20 dollars" is stamped on the face of such a $10 gold-piece it would be right and fair to use only fifty of such newly stamped pieces in cancelling an obligation to pay 25,800 gr. of standard gold; or, in other words, to pay 12,900 grains of standard gold in place of double that quantity, called for in the contract. Could anyone who has studied the money question in connection with the science of exchange be so foolish as to believe 232.2 grains of fine gold in the form of a coin with "20 dollars" stamped on its face will buy any more, in the marts of the world, than 232.2 gr. of gold in the form of a coin with "10 dollars" stamped on its face? Or, to put it in another form, as has been iterated and reiterated so often, a U. S. dollar is 23.22 gr. of fine gold, therefore 10 dollars must be 232.2 gr. of fine gold. But if a law is passed making 232.2 grains of fine gold '20 dollars' then one of such dollars would be 11.61 grains of fine gold or 12.9 gr. of standard gold, and as $1000 in gold coin of the present weight and standard of fineness is 25,800 gr. it would require 2000 of the new dollars to cancel an obligation to pay off the old (present) dollars. Could anything be clearer?

Again, "All that governments can do is to standardize and stabilize the relationship between gold and the mass of other wealth."

If Mr. Robbins would read understandingly (not after the manner of a "professional proof-reader") even parts of a very few of those 800 books and "digest and absorb" what he read, and if by "standardize and stabilize" he means to maintain a uniform ratio between gold and the mass of other wealth, he would learn that governments, so far, have been unable to accomplish any such thing. Instead, the ratio (relative-value) is determined by the exigencies of trade and commerce, wars, etc., as "exemplified'' in Stock Exchanges, Boards of Trade, and similar institutions all over the world, to say nothing of what is termed retail trade.

Again, ''As there is only a definite amount of gold in the world, some substitute for gold will be necessary, or it will be necessary to ascribe (give?) a greater exchange value to an ounce of gold'' and ''It seems to me that the maintaining of gold at its present value is going to increase the gravity of the present financial situation. The raising of gold to a higher valuation would ease present conditions and stimulate production of precious metals.''

Here is that same, old, false notion cropping out again, namely that governments can fix (''ascribe'') to an ounce or any other quantity of gold any old exchange-value they please. A suitable reference to even a particular one of those 800 books will refute (''confute'') this notion, for it is shown therein that gold is a commodity and its exchange-value is ''determined temporarily by supply and demand and permanently, on the average, by the cost of production.'' In round numbers, the world's production of gold for 30 years, 1866 to 1895 inclusive, has been estimated at 14,512,000 lb. troy, an average of 483,700 lb. per year; and from 1896 to 1917 inclusive, 22 years, 33,145,000 lb. or 1,506,000 lb. per year. In 1896, gold, as measured in supplies and commodities generally, has been estimated to have been worth nearly three times as much as it was in 1914. According to the foregoing figures, the average production for each of the 22 years was just about three times as much as it was per year for the previous 30 years, and during that 22 years its exchange-value steadily diminished. The state of war since 1914 has caused unnatural conditions, necessitating increased credit and an inflated currency, all of which have increased prices of other commodities abnormally, which means a corresponding reduction in the purchasing power of gold. Still, if the foregoing figures are substantially correct, the trebling of the yearly production of gold followed by an ultimate reduction of its exchange-value to one-third of its former worth may be something more than a mere coincidence. But it seems to prove conclusively that the Government stamp on a gold coin has nothing whatever to do with such a coin's purchasing power, excepting in so far as it indicates the weight of gold the coin ought to contain.

Again, ''Within Argentina the purchasing power (of gold?) is doubled.'' Argentina has an inconvertible depreciated paper currency with an exchange-value (as measured in gold) of less than one-half of its face value (44% according to one reference) and it follows, as a matter of course, that the purchasing power of a gold peso is double that of a depreciated paper peso.

In conclusion, permit me to make two more quotations and comment thereon.

''Between the lines of Mr. Benedict's concluding paragraph I read 'Shoemaker stick to thy last'. Ill-timed advice,'' etc.

The paragraph meant precisely what it said, and, as before stated, it was intended in a kind and friendly way, for Mr. Robbins is a stranger to me; it contains no innuendo whatever, nothing to be read between the lines. I regret very much if it was so worded that it could be misconstrued into giving ''Ill-timed advice.''

Again, ''I cannot feel that Mr. Benedict and his array of 800 books would alter my opinions unless coupled with confuting evidence.''

It seems needless to say that ample ''confuting evidence,'' sufficient to convince any reasonable person, is contained in that ''array of 800 books,'' and it awaits Mr. Robbins' pleasure. Or, if there is no prospect of his coming here soon, perhaps he could find in San Francisco 'The Principles of Political Economy', by J. S. Mill; 'Money and Banking', by Horace White; 'A Treatise on the Coins of the Realm', by Lord Liverpool; 'A History of Currency in the U. S.', by A. B. Hepburn; 'The Evolution of Modern Money', by W. W. Carlile, and read at his leisure such chapters in them as treat upon the subject of money and currency.

W. deL. Benedict.

New York, May 24.

The Internal Corrosion of Cables

The Editor:

Sir—In his article on this subject, Mr. W. F. Robertson makes the statement that Mr. Ben. B. Thayer informed him that the cables used by his company periodically were given an oil-bath heated by steam. This I have never seen done at the Anaconda mines but I have helped to tar cables elsewhere at the mines of Butte. Mr. Thayer could have informed Mr. Robertson that at the Butte mines the cables are tarred with pine-tar and a substance called 'cable-dressing' once a week and at some mines twice a week. If this was not done a cable would not last a month, let alone a year. Mr. Thayer is a practical miner as well as a theoretical one and he will probably recollect that the cables used at the Bi-Metallic mine at Granite, Montana, were tarred when he was foreman of that mine some 30 years ago, although there is no copper water there as at Butte.

I have worked in many mines where flat or round cables were used and they were tarred. I have never seen oil used on cables.

A. N. C.

Miami, Arizona, May 7.

Phosphate rock marketed in 1918, according to R. W. Stone, of the U. S. Geological Survey, was 2,490,760 long tons, valued at $8,214,463, compared with 2,584,287 tons, valued at $7,771,084, in 1917. Florida land pebble constituted 80% of the total output. Tennessee accounted for 374,535 tons of rock.

Grindstones sold in the United States during 1918 totaled 56,554 tons, valued at $1,262,602. This is a gain of 4% in quantity and 56% in value. Over 85% of the material used in the manufacture of grindstones was sandstone quarried in Ohio; the remainder was sandstone quarried in Michigan and West Virginia.

Exit the Blast-Furnace

By OLIVER E. JAGER

While this article applies particularly to the Anaconda reduction works, it would cause no great surprise to see other large smelters follow the same course, and decrease, or even discard, their blast furnace operation. The time-worn discussion of the respective merits of blast and reverberatory furnaces (except in particular cases) appears to be closed, as the trend of opinion for several years has been going steadily in favor of the reverberatory. In view of this, it is of interest to consider the conditions in general, and those at Anaconda in particular, that have led up to this radical change in smelting practice.

At Anaconda the intention is to use one or two small blast-furnaces as 'scavengers' only, doing practically all the ore-smelting in the reverberatories. This being so, the big Mathewson blast-furnaces will no longer be used, one of the 51-ft. units being already cut up into two 15-ft. furnaces from which it sprang, a remarkable instance of metallurgic atavism. The only reason for retaining these two furnaces is that the plant and equipment are already in existence, and it is cheaper to retain a portion of it than to build another reverberatory. The blast-furnace plant was scheduled to be shut-down over two years ago, but received a temporary lease of life through war conditions, which demanded the utmost possible production of copper. With the altered condition of the metal market a curtailment of output became necessary. The normal production at Anaconda is 26,000,000 pounds of copper per month; the present production is about 13,500,000 pounds. This reduction in output is accomplished by operating four reverberatories instead of seven, and at the same time shutting-down the blast-furnace plant entirely.

At the risk of recapitulation, there are herewith set out the principal disadvantages that have been urged against the two types of furnace under Anaconda conditions:

Blast-Furnace	Reverberatory
Unsuitable for fine ore.	Repairs are expensive.
Coke costs about twice as much as coal.	Coarse material must be crushed.
More labor and more water required than on roast-plus-reverberatory system.	Coal must be pulverized.
Higher cost of power.	Roasting is necessary; if much flotation concentrate is in the charge, dust losses must be combated.
No waste-heat credit.	Higher slag-assay, although less slag is made than in the blast-furnace.
Makes more slag, although of lower copper content than the reverberatory.	More capital is tied up in the bath of matte.

The case against the blast-furnace allows scarcely any argument. Even the last claim, of a lower slag-assay, is hardly tenable under present conditions at Anaconda. Formerly the regular ore-charge produced a slag carrying about 22% lime, but since the charge has become basic in character, silicious ores have to be added, and naturally the lime is held down as low as possible. The result of this is that the copper in the blast furnace slag has increased to about 0.3%.

The objections against the reverberatory will now be considered. While repairs are expensive, the cost must be compared with the tonnage smelted before a repair is necessary. When it is considered that the first 40 ft. of a reverberatory roof will not need repairing until 140,000 tons of charge has been smelted in the furnace, the per-ton cost of the repair is reduced to a reasonable amount. The question of crushing must be viewed in conjunction with the scheme of concentration, although it is true that material is crushed that might otherwise be separated for smelting in the blast-furnace. The old system of sending Butte first-class ore and coarse concentrate to the blast-furnaces has been dropped, since the method of dividing ores into classes has been abandoned, and the largest size of concentrate now made is ⅜ inch. With the adoption of flotation, calling for finer grinding, there is more fine concentrate made; in fact, it may be said that more tonnage is treated and more fine concentrate produced than ever before, all of which points to the reverberatory furnace as the logical appliance to be used in smelting. The cost of finer grinding at the concentrator is offset, in part, by the increased recovery made since that department was remodeled. The pulverizing of coal for firing, and the roasting of material to produce a suitable grade of calcine are two points about which there is little argument. They must be considered as necessary parts of the process, although the settling of the dust caused by roasting flotation-concentrate, while an important matter, can scarcely be held against the reverberatory furnace, being rather a consequence of the adoption of flotation. The two last objections on the list are largely overcome under present conditions of operation. The continuous-flow feature of the reverberatory furnace has reduced the slag-assay to a degree comparable with a blast-furnace slag, while the side-charging has diminished the matte-bath to a much smaller volume. These matters will be taken up at greater length in subsequent articles. The paramount question of cost is, of course, the main factor in the last analysis, and when the increased efficiency of the modern reverberatory using pulverized coal as fuel is considered, it is small wonder that the costs of crushing, coal-pulverizing, and roasting can be absorbed. In other words, reverberatory smelting, in spite of all the extra operations, is cheaper than blast-furnace smelting.

It is necessary only to make brief mention of the several stages of improvement through which the reverberatory has passed since it began to assume its present form. The original furnaces at the 'new works' at Anaconda in 1902 were 50 ft. by 19 ft. From 1903 to 1906 the length was increased, by stages, from 50 ft. to 115 ft. 10 in. The present reverberatories are 133 ft. 7 in. long by 22 ft. wide. Meanwhile calcine was being charged hot, and firing with fuel-oil had been developed; then came side-charging, and lastly, pulverized coal. Improvements in the manufacture of refractories have been of assistance in this development, and the addition of waste-heat boilers has furnished to the smelting operation a credit not to be despised. A ratio of at least 6.5:1 is obtained at Anaconda, and the present average daily total tonnage is 550, which gives 0.187 tons per square foot of hearth-area. With side-charging I am inclined to doubt the usefulness of this last figure for purposes of comparison, as it is practically impossible to determine the hearth-area, since some smelting undoubtedly takes place along the sides of the furnace. On the other hand, should the charge be sufficiently coarse to remain piled up at the sides of the furnace, the heap of material will project into the furnace and reduce the area by lessening the width. With the above tonnage and ratio, the efficiency of the reverberatory furnace is apparent, especially when the fuel question is considered. Firing with pulverized coal permits the use of coals whose ash content varies over a wide range. During a single month the ash has varied from 5 to 20%, which is worth the consideration of a smelter purchasing coal on a sliding scale according to its ash-content. The average ash in the coal now used is 13%, with a heating value of 11,000 B.t.u. per pound.

With no blast-furnaces in operation at Anaconda, it is of interest to consider the method of handling the coarse material that must be treated. The amount of this is small (about 200 tons per day); it consists of the following items: ladle-skulls and matte-runner cleanings; converter-floor cleanings; accretions from the hearths of roasting-furnaces; cleanings from the waste-heat boilers; Southern Cross ore and custom ore, all of which is crushed to pass a 4-in. opening. The Southern Cross ore and custom ore are further reduced to 2-in. size, and put through the roasters, which process, in the case of the first-named, is merely for the purpose of drying. Wet copper precipitates are also dried in this manner. Whatever material goes to the roasters, of course, reaches the reverberatories as part of the calcine. The matte-cleanings and other 'junk' are fed directly to the reverberatories in the usual manner, the only change that was necessary was the provision of a few charge-pipes of larger diameter; 12-in. pipes are being used for this, as against 6-in. for charging the finer material. It is planned to make all pipes of 10-in. diameter in future construction. The coarse charge is put into the furnace at a point about 15 ft. from the firing end; 40 tons per day is fed to each furnace, the large reverberatory that handles liquid converter-slag also taking its share. No difference has been noticed in the operation of the furnace on account of charging this coarse material, although it must be remembered that its introduction has a decided tendency to increase the copper in the slag, for the reason that it is high-grade, partly oxidized, and is not mixed with the other components of the charge.

When running at full capacity there would be double the amount of this coarse material, which, together with the silicious ore necessary to flux it, would provide sufficient charge for one 15-ft. blast-furnace all the time, and for two such furnaces part of the time, as provided for in the plan already mentioned.

So far as Anaconda is concerned, the blast-furnace has been definitely relegated to the 'scavenger' class. Its relative unimportance may be further realized from the fact that only 15.5% of the normal output of copper will be produced from material treated in blast-furnaces. Should any abnormal conditions again arise, it would, of course, be possible to produce extra copper by running more blast-furnaces, but the copper so produced would cost more than that credited to the reverberatory operations. With the general adoption of the flotation process, the copper smelter of today has to handle a greater quantity of fine material—a fact which certainly does not suggest more blast-furnaces— and when the increased efficiency and economy of the modern large reverberatory fired with pulverized coal or with oil is taken into account, there arises a set of conditions having an influence on present plant operation and future plant design that is incontestable.

The well-known firm of British soap-makers, Lever Bros. (Ltd.), is preparing to introduce a new method of paying wages, which the chairman of the company outlined thus at the recent annual meeting of shareholders: "As to payment of wages, we want to introduce a different method. Instead of our men crowding round the wage-office and waiting their turn, each man should have a little private banking account in a bank near his own house—not the firm's bank, but one of his own selection. We would advise our bank to credit each man from the pay-sheet with the amount of money he is entitled to receive for his wages. Under this system a man will draw out of his bank what he wants for his household expenses and what he does not need will rest in the bank. The amount left as deposit with the bank will be supplemented by an addition from the firm—we are favorably considering this—and this will give a man 5% on his money left in the bank; so that, instead of the money lying at home earning no interest, by adopting this system it will earn interest. Further than that, the tendency will be always to leave a little more each week in the bank, and I feel confident that if we can get this system universally adopted it will not only raise the workingman's position but add to his dignity, because, instead of crowding round a little pay-office, he will be led to become a saver, having money to invest in the business he is engaged in, or other businesses." Such a system might well be tried by mining companies.

Minerals Separation v. Butte & Superior

Decision of the Supreme Court of the United States, on writ of certiorari to the United States Circuit Court of Appeals for the Ninth District

Decision of the Supreme Court of the United States, on writ of certiorari to the United States Circuit Court of Appeals for the Ninth Circuit.

On June 2 Mr. Justice Clarke delivered the opinion of the Court, as follows:

This is a suit by the Minerals Separation, Limited, et al, plaintiffs below and petitioners in this Court, against the Butte & Superior Mining Company, defendant below and respondent here, to recover for infringement of United States patent No. 835,120, applied for May 29, 1905, and issued November 6, 1906, the validity of which was sustained by this Court in *Minerals Separation, Limited, et al. v. Hyde*, 242 U. S. 261.

The patent has been so frequently described in court proceedings* that it will suffice to say of it here, in the terms of the specification, that it "relates to improvements in the concentration of ore, the object being to separate metalliferous material, graphite and the like, from gangue, by means of oils, fatty acids, or other substances, which have a preferential affinity for metalliferous matter over gangue."

The patent contains 13 claims, which, for the purposes of this opinion, may be conveniently grouped, as follows:

(1) Numbers 1, 2, 3, 4, and 12, as 'fraction of one per cent. claims', because they call for the use of that amount of oil on the ore; (2) Numbers 5, 6, 7, 8, and 13, as 'oleic acid claims', because they are limited to the use of oleic acid in a small fraction of 1% on the ore—0.02-0.5%; (3) Numbers 9, 10, and 11, as 'small quantity of oil claims', all three of which were held invalid by the former decision of this Court. Only the five 'fraction of 1% claims' are involved in this case.

The respondent denied the validity of the patent and the claim of infringement.

The lower courts followed the decision by this Court and sustained the patent except as to the three 'small quantity of oil claims'.

The new evidence introduced on the validity issue is meager in amount, and of a character so unsatisfying that we see no reason for modifying our former conclusion.

The chief controversy in the case centres about the claim of infringement based upon the use of oil by the respondent in excess of 1% on (of the weight of) the ore, after the decision of the former case by this Court.

The evidence shows, and counsel now admit, that prior to the decision by this Court in December 1916, the respondent used, in its ore concentration operations, various oils in quantities less than one-half of 1% on the ore, but that from January 9, 1917, to the time of trial, with the exception of two or three weeks, it used oils of a composition which we shall discuss later on, in quantities in excess of 1% on the ore. In other respects its methods were substantially those of the patent in suit.

On this showing, the District Court found the patent infringed by the respondent, when it used oil in quantities greater than, as well as when it used it in quantities less than 1% on the ore.

The Circuit Court of Appeals held the patent infringed only when the respondent used oil in quantities equal to or less than, one-half of 1% on the ore, and it therefore reversed both of the holdings of the District Court, but allowed recovery for the period when less than one-half of 1% of oil on the ore was used.

The Circuit Court of Appeals derived its authority to limit the claims to one-half of 1% on the ore from the construction which it placed upon the following clause of the opinion of this court in the former case:

"The patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions,' 'amounting to a fraction of 1% on the ore.'"

The reasoning which carried two members of the Court to their conclusion was, that, as shown by the evidence of the patentees and the argument of their counsel, the amount of oil which is "critical," in the sense of marking the point of transition from the processes of the prior art to the process and discovery of the patent, is one-half of 1% of oil on the ore, and that therefore this

---

*British Ore Concentration Syndicate, Ltd., v. Minerals Separation, Ltd., 25 R. P. C. 741.

Minerals Separation, Ltd. v. British Ore Concentration Syndicate, Ltd., 27 R. P. C. 33.

Ore Concentration Company, Ltd. v. Sulphide Corporation, Ltd., Supreme Court, New South Wales, 31 R. P. C. 216, 217.

Ore Concentration Company, Ltd. v. Sulphide Corporation, 31 R. P. C. 206, Privy Council British Empire.

Minerals Separation, Ltd. v. Hyde, 207 Fed. 956, (D. C. Montana).

Hyde v. Minerals Separation, Ltd., 214 Fed. 100, (C. C. A. 9th Circuit).

Minerals Separation, Ltd. v. Miami Copper Co., 237 Fed 609 (D. C. Delaware).

Minerals Separation, Ltd. v. Miami Copper Co., 244 Fed. 752 (C. C. A. 3rd Circuit, including dissenting opinion of Judge Buffington, p. 775).

Court, by using the expression quoted, intended to limit the claims, not to a "fraction of 1%" but to a "fraction of one-half of 1% on the ore."

The specification of the patent points out that the proportion of mineral which floats in the form of froth varies with different ores and with different oily substances used and that simple preliminary tests are necessary to determine which oily substance will yield the best results with each ore. Of this feature of the patent this Court said:

"Such variation of treatment must be within the scope of the claims, and the certainty which the law requires in patents is not greater than is reasonable, having regard to their subject matter. . . . The process is one for dealing with a large class of substances and the range of treatment within the terms of the claims, while leaving something to the skill of persons applying the invention, is clearly sufficiently definite to guide those skilled in the art to its successful application, as the evidence abundantly shows. This satisfies the law."

Thus was it plainly held proper for the patentees to claim a reasonable degree of variation—"within the terms of the claims"—in the amount of oil to be used in the application of their discovery in practice, and that the restricting of the amount to a fraction of 1% on the ore was reasonable and lawful.

The two expressions "critical proportions" and "amounting to a fraction of 1% on the ore" being used, the former derived from the evidence and the latter from the claims of the patent, obviously, to the extent that they differ—if they differ at all—the language of the claims must rule in determining the rights of the patentees.

While in the former case this Court was not called upon, and in its opinion did not attempt, to define the scope of the claims, but was considering the patent only from the point of view of the invention and usefulness of the claimed discovery, nevertheless, the language quoted seems to indicate clearly enough that the opinion of the Court then was, as it is declared now to be, that as to the claims here involved the patent extends to and covers the use in the process of oils of the patent, in amounts equal to any fraction of 1% on the ore. The oleic acid claims are in terms limited to 0.02-0.5% on the ore. The Circuit Court of Appeals fell into error in the interpretation which it placed upon our opinion and its judgment in this respect is reversed.

Since the case must be re-tried, there remains to be considered the reversal by the Circuit Court of Appeals of the holding by the District Court that the use of oil by the respondent in excess of 1% on the ore constituted an infringement of the patent.

As we have said, prior to the former decision by this Court, the respondent used in its ore concentration process less than one-half of 1% of oil on the ore, and as to such practice infringement is clear, but from January 9, 1917, to the time of trial, with slight exceptions, it used in excess of 1% on the ore, and it is necessary to consider only the operations during this latter period. The oil used during this period, was a compound, varying in composition from time to time, but we agree with the District Court in selecting as typical a mixture made up of 18% of pine-oil, and the remainder of petroleum products or derivatives—12% of kerosene oil, and 70% of fuel-oil. Of this compound there was used 30 pounds to the ton of ore, which would be 1.5% on the ore. As thus stated, without more, it is obvious that the use of such an amount of oil, would not infringe the claims of the patent which limit the oil to be used to a fraction of 1% on the ore.

But the contention of the petitioners, approved by the District Court, was, and now is, that kerosene and fuel-oil were inert and valueless, if not harmful, as used by the respondent in the process and rendered the recovery less than it would have been if the pine-oil only had been used; that they were added solely to carry the content of oil beyond the prescribed fraction of 1% on the ore, in the hope of technically avoiding infringement; and that essentially in its operations the respondent used the process of the patent with 0.27 of 1% of pine-oil on the ore, and therefore infringed it.

The respondent replied that it was not true that kerosene and fuel-oil were inert and useless, and asserted that they were oils of the patent, "having a preferential affinity for metalliferous matter;" that the patentees by the claims of their patent had limited their exclusive right to the use, in the process, of any oil or oily substance having such an affinity, but in an amount not greater than a fraction of 1% on the ore, and that, therefore, the process of the respondent, in which more than 1% of oil on the ore was used, did not infringe the patent.

The entire evidence in the Hyde case was introduced on the trial of this case, and whether the petroleum products or derivatives used by the respondent were oils within the scope of the patent must be determined from the record now before us.

It is admitted that petroleum products are "oils having a preferential affinity for metalliferous matter."

In each of the four claims of the "complete specification" of the British patent, filed by the same persons who were patentees of the patent in suit, on June 3, 1905, "petrol" is given as an equivalent of oleic acid in the process. This appears in the statement, repeated in each claim, that the ore and acidified water shall be mixed or agitated with "a small proportion of an oily substance such as oleic or petrol, amounting to a fraction of 1% on the ore." Petrol is the name used in England for gasoline.

The claims of the patent in suit which we are considering call for the use in the process of an "oily liquid," "an oily substance," and in the twelfth claim simply of an "oil." These expressions are said by Professor Chandler, an expert for the petitioners, much relied on in the Hyde case and in this, to include petroleum products.

Higgins, one of the experimenters who discovered the process in suit, and who is much relied upon by the petitioners as an expert witness in both cases, testified as follows in the Hyde case:

Q. Have you since found it possible to use other oils than oleic acid with the result of producing a froth?

A. Yes.

Q. What other oils?

A. I have obtained satisfactory results by the use of petrol and certain proportions of distillate of crude petroleum, such as Cosmos oil.''

and he said "Cosmos oil" is "a petroleum distillate."

Chapman, an engineer and a witness for the petitioners in the Hyde case, testified that he had obtained good recoveries in the laboratory and in commercial practice, from the ore of the Braden mine, in Chile, using three pounds of Texas fuel-oil to one pound of American wood tar oil per ton of ore. Texas fuel-oil is petroleum.

Graninger, an engineer employed by one of the petitioners in installing its flotation plants, testified in this case that in a mine in British Columbia he used a mixture of oil, 75% of which was derived from petroleum.

There is much more of the same character from witnesses for the petitioners and the evidence of the respondent is strongly to the effect that petroleum products are useful and efficient and have been widely used in the process in laboratory and commercial practice.

Without quoting more from the record before us, we must conclude that when the patent in suit was obtained, and even until the testimony in the Hyde case was closed in 1912, petroleum products were recognized by the petitioners, and that they are still used, as oils, efficient, and useful in the process of the patent in suit. Much of this evidence is especially impressive because the papers from which it is derived were written and the witnesses testified before the question as to petroleum, now made in this case, was raised or discussed.

While we thus conclude that petroleum and petroleum products are oils useful in this process of the patent, it is also clear that they are not as highly efficient as pine-oil and several other oils and combinations of oils, which, in the nomenclature of the record are called "frothing oils," and also that better results would probably have been obtained by the use of less than 1% on the ore, of pine-oil alone, than were obtained by the respondent with that oil in combination with the larger amounts of petroleum products. And this presents the further question necessary to a decision of the case, viz.:

Does the use of a more efficient, in combination with a less efficient, oil of the patent, constitute infringement, where the former is used in an amount within the limits of the claims but the combined amount is in excess of such limit, and when the amount of the more efficient oil used would probably produce better results from the process than are produced witth the combination of oils?

To answer this question requires a consideration of the state of the prior art as it was when the discovery of the patent was made, and of the scope of the claims which we are considering.

It is always difficult to recover the realities of a situation long past, such as we have here, but it is especially difficult when the importance of the discovery has led, as in this case, to extensive improvements in mechanical appliances for utilizing the invention and to large additions to the knowledge of the adaptability to the process of various oils, singly and in combination.

We held in the former case that the patentees came late into the field of ore concentration investigation and that their discovery rests upon a prior art so fully developed that it was "clear from the record that approach was being made slowly but more and more nearly to the result which was reached by the patentees of the process in suit in March 1905," and that their final step was not a long one.

Such a patent, in such a field of investigation, must be construed strictly, but candidly and fairly, to give to the patentees the full benefit, but not more, of the disclosure of their discovery which is to become a part of the public stock of knowledge upon the expiration of the patent period, and which was the consideration for the grant to them of a patent monopoly.

With the state of the prior art in mind, we come to consider the nature and extent of the disclosures of the patent in suit, but only with respect to the kinds and quantities of oil which may be used in the process.

The specification recites that the invention of the patent relates to an "improvement" upon prior processes employed in ore concentration "by means of oils, fatty acids, or other substances which have a preferential affinity for metalliferous matter over gangue."

Next come the specific disclosures required by the patent law (R. S. 4888), which are intended to describe the advance which the patentees claimed to have made from the prior art Cattermole agglomeration of metalliferous matter into granules, which separate from the gangue, and sink to the bottom of the pulp under treatment, to the discovery of the patent in suit, with its metal bearing froth, rising to the surface of the pulp. Here is the essence of the discovery and it is announced in these terms:

"We have found that if the proportion of oily substance be considerably reduced, say to a fraction of 1% on the ore, granulation ceases to take place, and after vigorous agitation there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum."

This is followed by the description of three "factors" on which "this tendency is dependent," viz: slight acidification, heat, and fine pulverization of the ore, and then the disclosure concludes with the statement that the proportion of mineral which floats in the form of froth varies with different ores and with different oily substances, and that a simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired.

The only additional statement contained in the specification, which is in the nature of a disclosure, is found in the description of the example of the application of the invention, in which it is stated that the "froth or scum" derives its power of flotation mainly from the inclusion of air-bubbles introduced into the mass by agitation, such bubbles or air-films adhering only to the mineral particles which are coated with oleic acid.

There remain the claims of the patent, in which the Act of Congress requires that the patentee shall "particularly point out and distinctly claim "the . . . improvement . . . which he claims as his invention or discovery." And of these this court has said in *Keystone Bridge Co.* v. *Phoenix Iron Co.*, 95 U. S. 274, 278:

"But the courts have no right to enlarge a patent beyond the scope of its claim as allowed by the Patent Office. . . . As patents are procured *ex parte*, the public is not bound by them, but the patentees are. And the latter cannot show that their invention is broader than the terms of their claim; or, if broader, they must be held to have surrendered the surplus to the public."

And in *White* v. *Dunbar*, 119 U. S. 47, 52:

"The claim is a statutory requirement, prescribed for the very purpose of making the patentee define precisely what his invention is; and it is unjust to the public, as well as an evasion of the law, to construe it in a manner different from the plain import of its terms."

And see *Motion Picture Patents Co.* v. *Universal Film Co.*, 243 U. S. 502, 510.

Since we are concerned only with the five "fraction of 1% claims," and since the question we are discussing relates only to the use of petroleum products, we need consider them only with respect to the amount and character of the oil prescribed, and, as they are substantially identical, we quote the first as typical:

"The herein described process of concentrating ores which consists in mixing powdered ore with water, adding a small proportion of oily liquid having a preferential affinity for metalliferous matter (amounting to *a fraction* of 1% on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation."

The first three claims declare that, so far as oil is concerned, the discovery resides or consists in "adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter, amounting to a fraction of 1% on the ore:" the fourth claim differs only in substituting the word "substance" for "liquid" in the first three; and the twelfth claim provides for carrying out the process with "oil in water containing a fraction of 1% of oil on the ore."

From this consideration of the terms of the patent as written, it is apparent that it makes no differentiation whatever, either in the claims or in the specification, among the oils having a preferential affinity for metalliferous matter, and that its disclosure, to which the petitioners must be limited, is, that when a fraction of 1% on the ore of any such oil is used in the manner prescribed, there will be produced a metal-bearing froth, the result of the process. No notice is given to the public, and it is nowhere "particularly pointed out" in the claims, that some oils or combination of oils, having a preferential affinity for metalliferous matter, are more useful than others in the process, or that some may be used successfully and some not, or that some are "frothing oils," a designation not appearing in the patent, and that some are not. The patentees discovered the described process for producing the result or effect, the metal-bearing froth, but they did not invent that result or froth,—*their patent is on the process, it is not and cannot be on the result,*—and the scope of their rights is limited to the means they have devised and described as constituting the process. *Corning* v. *Burden*, 15 How. 252, 268; *LeRoy* v. *Tatham*, 14 How. 156, 175; *Fuller* v. *Yentzer*, 94 U. S. 288; *Robinson on Patents*, Section 149.

The patent in suit was applied for in this country on May 29, 1905, within a few weeks after the discovery which it embodies was made, and whether from haste or lack of investigation, from the necessity of meeting the exigencies imposed by the prior art or from a desire to make the claims as comprehensive as possible, this discussion of its terms makes it clear, that the only disclosure as to the kind and amount of oil which the patentees made to the public as necessary to the practising of their process is that it must be an oil or oily substance, or oily liquid having a "preferential affinity for metalliferous matter," and that it shall be limited in amount "to a fraction of 1% on the ore."

It is argued that the provision of the claims that the mixture prescribed, of oil, water, and ore, shall be agitated until the oil-coated mineral matter forms into a froth, serves to differentiate the "frothing oils" from others having the required preferential affinity for metalliferous matter but which, when agitated in the mixtures, may not produce the characteristic froth, if any such there are, and that a proper construction of the patent limits it to such "frothing oils" and renders the use of them in a fraction of 1% on the ore an infringement when used with "non-frothing oils" having the required affinity in amounts sufficient to make the combination exceed the quantity limit of the patent.

To give such a construction to the patent would subordinate the clear description contained in it of what are oils of the process, to an implied and vague description and classification which would leave the whole subject again at large, to become a field for further experimentation, without definition in the patent of what oils or froths would satisfy it. So interpreted the patent could not reasonably be said to contain a disclosure of the discovered process in the "full, clear, concise and exact terms" required by law (R. S. 4888) and the claims might conceivably be said to fall short of "particularly pointing out and distinctly claiming" any discovery at all within the meaning of the Act of Congress.

Thus when to our former conclusion that the respondent used an efficient oil of the patent, we add the further conclusions, derived from a study of its terms, that the patentees failed to differentiate among the oils described in the patent, we must conclude that it is impossible for the courts to distinguish among them, as more or less efficient in the process, without amending the claims of the patent and this they are powerless to do.

We are confirmed in the conclusion thus arrived at by the evidence which the patentees in the *Hyde* case, petitioners in this, introduced to show that their discovered process could not be made operative when more than a fraction of 1% of oil on the ore was used, and that the use of a greater amount would not produce the typical froth which results from it—this without differentiation among the oils described in the patent, save as to their varying adaptability to different ores.

Thus, Ballantyne, a metallurgist and the patent agent who prepared the patent specifications for the petitioners, when called by them as an expert witness, testifies to intimate relations with the patentees and with their investigations before and since the patented discovery was made, and says:

"I have never seen the agitation-froth process successfully carried out by the use of an amount of oil equal to practically 1% by weight on the ore, and in my opinion 0.9999% of oil would not be a proper quantity (that is to say a suitable and economical quantity), as contemplated by the patent, and would not, therefore, be a suitable fraction of 1%, as contemplated by the patent."

Liebman, an expert much relied upon by the petitioners, testified:

"Q. I understand from your answer . . . that you have never in your operations . . . obtained any floating mineral-bearing froth when using an amount of oil, or other selective agents, amounting to more than 1% of the weight on the ore. In order that there may be no misunderstanding, will you state whether I have understood you rightly?

"A. That is my recollection."

John Ballot, one of the patentees, testified that he had never seen a froth of the character produced by the patent in suit using a pulp containing more than 1% of oil.

There is much more of similar import in the record. This, however, will suffice, adding only the record of a remarkable incident which occurred in this Court during the argument of the *Hyde* case by Mr. Kenyon for the petitioners:

"Mr. Justice McReynolds: I would like to ask you when in this process of reducing oil your invention came into existence?

"Mr. Kenyon: At about one-half of 1% of oil.

"Mr. Justice McReynolds: Before you got to the one-half of 1% did you have any invention?

"Mr. Kenyon: We were passing from the region of Cattermole, which was a distant—

"Mr. Justice McReynolds: I want to know when your invention came into existence?

"Mr. Kenyon: This invention was not reached, I should say, from those figures, until about 0.5, that is one-half of 1% of oil was reached.

"Mr. Justice McReynolds: At 1% you had no invention?

"Mr. Kenyon: No.

"Mr. Justice McReynolds: At one-half of 1% you did have invention?

"Mr. Kenyon: It began to come. Remote, but it began to come. At 0.3 of 1%, the float vastly increased. At 0.1 of 1%, the float again vastly increased.

"Mr. Justice McReynolds: When this float has more than one-half of 1% of oil it does not infringe?

"Mr. Kenyon: It does not infringe.

"Mr. Justice Pitney: What have you to say in answer to what Mr. Scott said the other day to the effect that 1.8%, or perhaps more, of oil would give the same result with increased agitation?

"Mr. Williams: Absolutely no.

"Mr. Kenyon: It would not."

While parties should not be held rigidly to statements made by their counsel in the stress of argument, even when replying to questions from members of the Court, nevertheless these statements from leading counsel in charge of the *Hyde* case and of this case, are impressive and significant.

This and much more of like character in the record brings us unhesitatingly to the conclusion that the scope we have given to the patent, based upon an interpretation of the language of the claims, is justified also by the evidence in the case and that it is, in fact, that which the petitioners and their counsel, until very recently, placed upon it in full confidence, that the essence of the discovery lay to such an extent in the use of a small amount of oil, such as is described in the patent, that the result could not be obtained with more than a fraction of 1% on the ore.

It must be added that the evidence is far from satisfying that the results of the respondent's process was, in fact, that peculiarly superior quality of metal-bearing froth characteristic of the patented process when worked with a fraction of 1% on the ore. The evidence, otherwise doubtful on the point, is rendered especially so by the testimony introduced by the petitioners, and not contradicted, that a computation on the basis of the tonnage of ore treated by the respondent shows that if the process as practiced by it after January 9, 1917, had been used through the year it would have involved a loss of over a million dollars in increased cost of oil and in diminished recoveries, as compared with what the results of operation would have been for the same time using the process of the patent as practiced by the petitioners. It is difficult to see how a process so wasteful and inefficient as that of the respondent is thus proved to be can be other than substantiallly different from that of the petitioners.

It is vaguely suggested in the testimony for the petitioners that there was some peculiarity in the composition of the ore of the respondent, or in the treatment of it, which resulted in the presence of "clayey gangue slimes" which absorbed an unusual quantity of oil and that this contributed to render it possible to produce the results of the patented process when more than the prescribed fraction of 1% of oil on the ore was used.

It is hard to see how this, if true, would be of value to the petitioners, but the evidence is quite too indefinite in character and meagre in extent to be accepted as the basis for the judicial determination of such a claim.

The respondent contends that the disclaimer filed by the petitioners with respect to the three claims held invalid by the decision of this Court in the former case, was so delayed and is so evasive in form that it is invalid and that, for this reason, the petitioners should not be permitted to further prosecute this suit, under the provisions of R. S. 4917, 9422.

The decision holding the three claims invalid was rendered on December 11, 1916, and the disclaimer was recorded on the 28th day of March, 1917. Having regard, to that fact that the owners of the patent in suit resided in a foreign country, and to the war-time conditions of communication then prevailing, the entry required by law was not "unreasonably neglected or delayed." While the wording of the disclaimer borders on finesse, we do not think it can be interpreted as giving any rights under the patent greater than may be legitimately obtained under the claims held valid, and we therefore deem it sufficient to meet the requirements of the statutes cited.

It results that the decree of the Circuit Court of Appeals that the respondent infringed the patent only when using one-half of 1% or less of oil on the ore must be reversed, but that its implied holding that the use made by respondent of petroleum products and pine oil in excess of 1% on the ore did not constitute infringement must be sustained. The cause is remanded to the District Court for further proceedings in conformity with this opinion.

Removal of Amalgam From Plates

By A. J. HERALD and A. KING

[*]USUAL METHOD AND ITS DISADVANTAGES. It is common practice in many mills to clean the amalgam from the steaming of plates, grinding it up with additional mercury, removing iron, pyrite, etc., in the ordinary way, and then press it into cakes ready for the retort. By this method a clean amalgam in a convenient form for the retort-pans and containing 27 to 30% fine gold is obtained, the amalgam in the process having taken up an additional 18 to 25% of mercury, practically all of which is ultimately recovered from the retort. Where large quantities of steam amalgam have to be handled this method has disadvantages obvious to those acquainted with the operation; several white men, including responsible officials, are tied to the amalgam-room continuously for a number of hours; other work and supervisory duties having to be neglected in the meantime, and the labor involved in carrying out the cleaning and pressing of this product is by no means light. There is always a certain amount of risk and danger in having several thousand ounces of amalgam exposed during the various stages of the process. The retorting and smelting of this cleaned amalgam present no difficulty however, bullion of 890 gold fineness being commonly obtained.

PROPOSED METHOD. The method which the authors have adopted, after slight variations, is as follows: The plates to be steamed are made reasonably clean by washing down and removing iron, etc. (by scraping lightly, if necessary), before steam is applied. After steaming and scraping the crude amalgam is introduced at once into the locked receptacle in which it is to be conveyed ultimately to the melting-room, no grinding with additional mercury being done. When charging the retort-pans a small quantity of oxidizer (such as manganese di-oxide) is sprinkled over the amalgam. The amount of oxidizer used is about 0.5% on the weight of amalgam, and is not enough to cause any ebullition or affect the bullion in any way except to oxidize the iron present in the amalgam so that it may be absorbed readily into the slag as a silicate during the subsequent melting of the retorted bullion. The retorted bullion will probably look impure on account of the iron oxide present, but will yield clean bars of 888 to 891 fineness without refining or skimming.

ADVANTAGES OF PROPOSED METHOD. These are obvious and important, particularly when a large quantity of amalgam has to be handled at a time. The amalgam has only to be weighed after it is taken off the plate, and can then be locked away immediately, risks of all kinds and danger of exposure being therefore reduced to a minimum. Labor is also reduced, no over-time being necessary even when 10,000 oz. of amalgam are steamed. It is also obvious that a smaller stock of mercury can be kept when steam amalgam does not require grinding and cleaning. Further, since the capacity of a retort for cleaned or uncleaned amalgam is practically the same, a greater weight of bullion is obtained from a retort full of the latter, as will be apparent from the figures already given.

If, for convenience of handling, it be desired to get the amalgam into a coherent cake this may be done by mixing the amalgam with water and then pressing. This involves more handling, exposure, and time, and does not seem necessary.

It will be noted that the method advocated is a simplified form of the older method, and in that respect might be taken as an example of an advance in practice by elimination of certain operations which were at one time considered essential rather than by further elaboration of the method. A parallel case is that of eliminating the risks involved in intimately mixing calcined gold-slime with fluxes preparatory to crucible-smelting by introducing the slime and flux into the crucible in separate layers.

DOMESTIC CRYSTALLINE GRAPHITE marketed in 1918, as shown by the final figures compiled by H. G. Ferguson, of the U. S. Geological Survey, is indicated in the table below:

State	Pounds	Value
Alabama	7,795,475	$999,152
New York	3,266,518	273,188
Pennsylvania	1,010,000	112,059
California	782,046	70,400
Montana		
Texas		
	12,861,830	1,454,799
Sales in 1917	10,564,080	1,074,398

A Peculiar Experience in Shaft-Sinking

By ARTHUR JARMAN

INTRODUCTION. At the Waihi Grand Junction mine, in New Zealand, all the hoisting of rock, ore, and men is done through one shaft, which has four compartments besides the pump-and ladder compartment. Early in 1912, the ore and rock hoisted per day averaged over 400 long tons and the lowest level was at 1098 ft. An air-shaft, 6 by 4 ft. in the clear, connected with the 194-ft. level and was used for ventilation only, being equipped with a Sirocco fan rated at 40,000 cu. ft. per minute. To facilitate the exploration and working of the eastern portion of the company's ground, it was decided to sink another shaft about 1150 ft. east of the main shaft, a suitable site being available, unencumbered by buildings and well situated with regard to the underground workings.

The first 80 ft. of sinking was made difficult by a pocket of mud encountered in the north-western corner of the shaft at a depth of 35 ft. An account of this work is given herewith.

PRELIMINARY WORK. Before excavating for foundations or erecting any gear, a trial pit, 5 by 5 ft., was sunk. This passed through firm clay, and at 22 ft. had bottomed in the so-called pumice-rock of the district, which is really a much altered rhyolite with large porphyritic crystals.

The surface of the rhyolite dipped north-west about 15°, but at the proposed site of the engine-house it was exposed, as shown in plan on Fig. 1, and it is also seen at other places south and east of the shaft-site within a radius of 100 feet.

As everything appeared satisfactory, the shaft was started at full size, and was sunk and timbered for 11 ft., there being two compartments 3 ft. 9 in. by 6 ft. and one 6 ft. 6 in. by 6 ft. in the clear, the latter being for pump-and-ladder way. An old head-frame was erected, together with a hoisting-engine, boiler, economizer, and chimney, after which sinking was resumed.

THE RUSH OF MUD. When the fifth set of timber was put in, at a depth of 25 ft., the ground was firm with the exception of the north-western corner, in which the clay had given place to a soft white mud, the surface of the rhyolite having dipped almost vertically along the line *AB* as shown in the plan, Fig. 1. On prodding with a drill, the mud appeared to occupy a large cavity, and therefore particular attention was paid to this corner. Slabs were set closely behind the timber, and sacking packed behind them to stop the mud from running. The shaft-engineer inspected the corner every 45 minutes or so, and sinking and timbering proceeded very slowly, the mud being soft and troublesome. After sinking about 10 ft. in this way (total depth, 35 ft.) soft white mud entered and filled the shaft to a depth of 15 ft in two or three seconds, the inrush being so sudden as to completely submerge one of the men. The others, however, sprang onto the ladder and timbers. On rising to the surface of the mud, the unlucky one was quickly pulled out, rather scared, but fortunately uninjured except for some bruises.

Simultaneously with this inrush of mud, the surface gave way under the north-western leg of the head-frame, the concrete foundation-block 5 by 4 by 6 ft. and surrounding ground falling six feet along the outline marked *C C C* on the plan, the concrete block disappearing under the subsoil.

The head-frame was thrown out of plumb, and the 'rub' of the falling ground dragged the shaft-timbers down 26 inches at the north-west corner and 19 inches at the north-east corner, the bearer under the collar-set being left without support at its western end. Fortunately, the leg affected was one on the side remote from the engine-house, so that stresses due to hoisting would have the effect of pulling the leg upward.

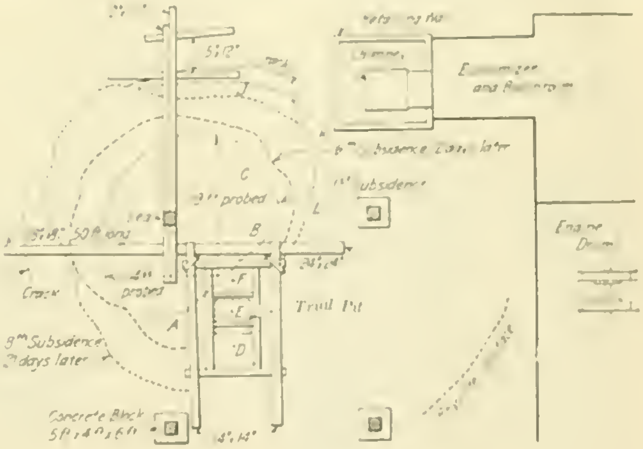

FIG. 1

THE SUBSIDENCE. The hole at the surface was filled with subsoil as quickly as possible in order to support the walls of the cavity and prevent them from crumbling away. At the same time, slabs that had slipped down from behind the two top sets of shaft-timbers were renewed, so as to keep the soil from falling down the shaft. Support was then arranged for the shaft-timbers as shown in Fig. 3 and Fig. 4. An old leg of a head-frame was laid across the pit, or subsidence, to bridge the space. This timber was 50 ft. long and 24 by 24 inches, tapering to 18 by 18 inches at the smaller end. It was placed east and west at the north end of the shaft, and had more than 10 ft. of bearing surface at each end.

Upon this were laid 16-ft. baulks 14 by 14 inches, one along the eastern side and the other along the western side of the shaft, and from the northern ends of these the northern bearer of the collar set was suspended by straps and inch bolts; upon tightening these, the strain upon the shaft-timbering was relieved, the west end being raised 19 inches and the east end 7 inches. See plan, Fig. 1, and elevation, Fig. 3.

The suspended leg of the head-frame then came in for its share of attention. Two bearers, 12 by 12 inches and about 40 ft. long, were placed under it, resting on the 24 by 24-in. timber at one end, and at the other (north) end supported by timbers resting upon the ground. The ground here showed small cracks running parallel with the edges of the subsidence, hence the use of these timbers to obtain a bearing surface. The leg was then raised 15 inches by driving wedges under it, until the head-frame was straightened sufficiently to allow hoisting to proceed. The centre-line remained rather more than an inch out of plumb.

The slabbing of the shaft-timbers having had further attention, the mud was bailed out by hand. The trucks used for sinking were made without a door so that they were available for bailing.

Sinking Resumed. Mud flowed into the shaft at the corner on the slightest provocation, but by excavating the rest of the shaft first, and forcing slabs into the soft mud at the north-western corner, by aid of jacks, it was possible to get a new set of timber into position and afterward slab the ground behind it. The mud was steadily on the move, oozing slowly nearly all the time, and had to be watched constantly by one of the party. It had the consistence of thick syrup. If its movement increased seriously, all hands retired 6 or 10 ft. up the timbers until it quieted down again. This movement was from the floor just inside the timbers in the north-western corner. Slowly, and with difficulty, a set would be placed in position and slabs secured behind it. Several rushes of mud occurred, and it was evident that the mud-hole was much larger than was at first thought. Over 100 cubic yards of filling had already been used.

Size of the Mud-hole. It therefore became necessary to find out what the extent of the hole was, as it might be necessary to abandon the shaft or seriously modify the procedure then being followed. The shaft was about 40 ft. down, and the expenditure upon it amounted to over $20,000, including equipment.

Probing by means of ¾-in. pipe, screwing lengths together as required, showed an almost vertical wall 32 ft. deep and a cavity approximately 15 by 20 ft. in width. See Fig. 1 and 2. The next step was to ascertain whether this cavity extended under the other compartment of the shaft. Three holes therefore were put down, using a 4-in. star-bit drill and a sludge-pump, one hole in the centre of each compartment, as shown in the vertical section, Fig. 1. The results were as follows:

D — pump and ladder-way compartment.

5 ft. of firm rock 'pumice'.
14 ft. of softer rock, progress one inch per stroke.
7 ft. of firm rock.

26 ft. total.

E — south winding compartment.

10 ft. of firm rock.
8 ft. of soft rock, progress two inches per stroke.
22 ft. of firm rock.

40 ft. total.

F — north winding compartment.

10 ft. of firm rock.
8 ft. of soft 'pug', or gouge.
22 ft. of firm rock.

40 ft. total.

The walls of *D* and *E* stood well, and looked quite clean after clearing them with the sludge-pump. *F* did not stand well, the slime oozed out at the top from time to time, thus proving it to be directly connected with the mud-hole as shown in Fig. 1.

From the probing already made it appeared that the mud-hole would have a capacity of at least 414 cu. yd. (measurement of the filling used showed 409 cu. yd. excavated; allowing 10% increase, we get 450 cu. yd., but this measurement was only obtainable after all the difficulties were overcome and the filling material had stopped subsiding).

Procedure Adopted. From the size of the mud-hole and the fact that it would continue at the corner of the shaft for another 30 ft., it was evident that a large mass of mud had to be displaced and would come into the shaft from time to time. Sinking was continued slowly, filling the subsiding ground at the surface to support the sides of the hole and to thicken the mud by making it drier. The latter object was not attained, however, as the soil and mud rarely mixed, the mud that forced its way into the shaft being rarely discolored by the soil or the clay.

The northern end of the shaft was always left until the rest of the shaft was excavated and ready for timbering. If mud was troublesome, a dam or barrier of ground was left to keep the mud in check in the northern compartment while excavating the southern end; or a rough timber dam was rigged. The mud was baled out from behind this at intervals. When excavating the north end, slabs had to be forced into the mud to support it as far as possible; and, when placing timber in position, one man would shovel or scoop the mud out with his hand while another watched the mud coming up slowly from the floor. A mud-rush would be preceded by an increased movement from the floor, the mud squeezing up alongside the line *AB* in plan, Fig. 1, like a gigantic sausage, which was too soft to retain its shape when released. When this began to move at one to two inches per second, the whole party would take to the ladder-way and timbers. After expelling about 30 to 50 cu. ft. the mud would become more liquid, and with a 'flip-flop-flip-flop' the shaft would be filled to a depth of 5 to 10 ft. in two or three seconds, this representing

700 to 1400 cu. ft. of mud. The rustling of the earth against the slabs told of the subsidence of the filling overhead, and very soon the call would come "Below there! the ground's sunk another 3 ft.," or whatever the amount might be.

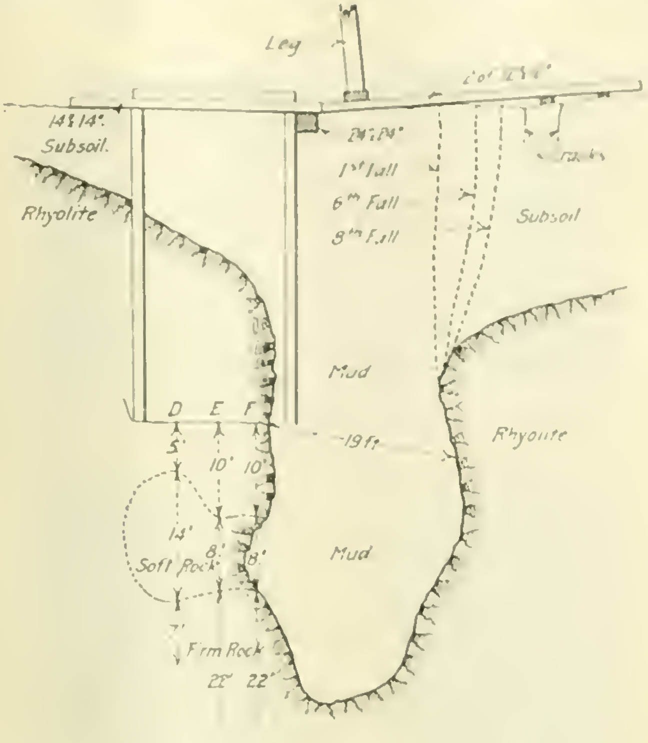

Fig. 2

As slabs were apt to be displaced and become dangerous to the workers below, panels were substituted for them, with good results, because these were very seldom displaced. After a 'rush', all hands commenced filling at the surface, bailing being postponed until the filling was in a forward state.

The timbering, shown in Fig. 3 and 4, illustrates the difficulty of supporting the north-western corner, the bearer breaking as shown in the drawing, Fig. 4, and the wall-plate on the western wall of the sixth set breaking also. The lowest set was therefore packed and wedged up from the floor of the shaft particularly along the western wall, thus relieving the strain upon the timbers higher up. The western side was cut last of all, and as soon as a new set had been put into position with its struts and packing-pieces the western side was again wedged up and jacked up from the floor.

Above the eighth set a central bearer 14 by 12 inches was placed having 18 inches of bearing at each end. No. 7 set was wedged up from this, the packing-pieces below were removed and No. 8 was then hung from No. 7 in the usual way. Pressure made it necessary to use 6 by 12 in. and 8 by 12 in. dividers, and insert them as soon as the set was in position. Hence a short cross-cut, or 'cuddy', was driven into the ground for 10 ft. south of the shaft to enable the 17 ft. wall-plates to be brought into position, otherwise they could not be lowered past the dividers. Later, another cross-cut was required for the same reason, after which the side pressure eased off.

Using a central bearer as above, the wall plate or side-timber of each set on the western wall supported the downward pressure at the northern end by acting as a cantilever, the northern being the free end. The sixth set broke and the tenth also, later on, as shown in Fig. 4, and extra packing had to be used to support the northern end in each case.

This tenth set was supported by a 14 by 12 in. bearer with 1 ft. of bearing at each end, and the breaking of No. 10 wall-piece was due to a larger rush than usual, which caused the timber at the north-eastern corner to subside slightly, and the ground at the surface to subside two feet along the line *JKL*, which was uncomfortably near the foundations of the chimney. The roots and limbs of a white pine projected from the mud and had to be sawn away before the next set of timber could be placed in position.

After putting the twelfth set, at 50 ft. depth, a mud-rush occurred over-night, and it was then found that

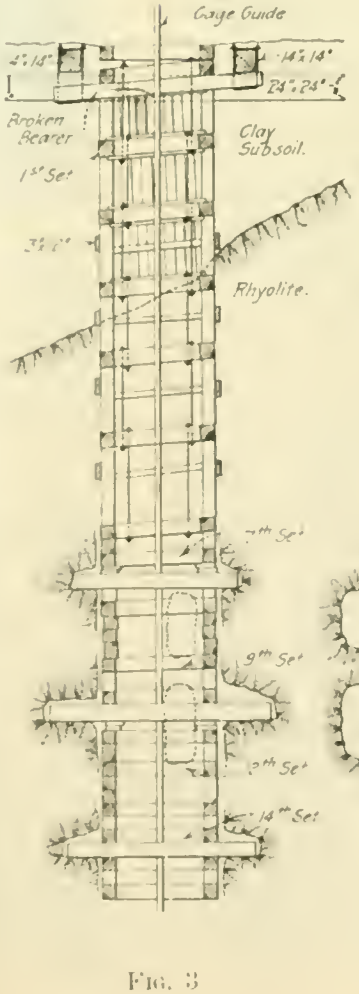

Fig. 3

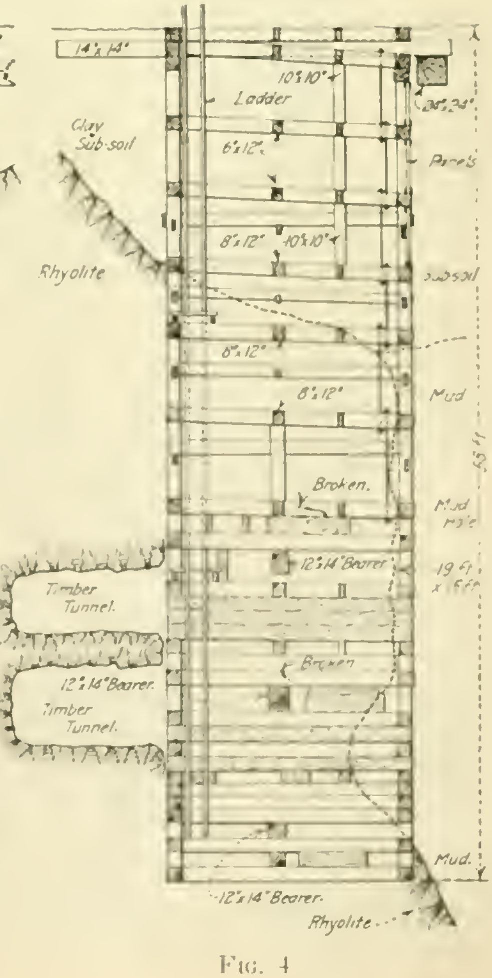

Fig. 4

the bearers at the top of the shaft were free from strain, the nuts being loose on the suspension bolts from the temporary 14 by 14-in. bearers at the sides of the shaft at the northern end. From this we knew that the two special centre-bearers under the seventh and tenth sets had relieved the upper sets from the weight and drag of the north-western corner. Sets were placed two feet apart and a central bearer 14 by 12 in. was put under the fourteenth set.

Another run of liquid slime occurred, after which probing showed the depth of mud in the corner of the shaft to be only 4 ft. and the farthest distance out sideways only 8 ft. At 58 ft. deep, the sixteenth set was put in, the whole of the ground in the north-western corner now being firm rock. Sinking was continued down to 71 ft., when the northern corners were tested by drill-holes and found to be good firm rock, after which hitches were cut and bearers 14 by 18 in. by 11 ft. were put in at each end and the timbers supported upon these. The set at the top of the shaft was straightened, new posts inserted, and slabbing renewed where required. It was found that the north-western corner had to be raised a further 19 inches and the north-eastern corner 7 inches to bring them level, and the leg of the head-frame was set up a further 12 inches to line up. Filling material was spread over the area that subsided as shrinkage required it, and this ground became firm.

Conclusion. It had taken 11 weeks to sink the last 43 ft., and now, at 78 ft. deep, our mud troubles being over, a contract was let for sinking. Good progress was made, 46 ft. in the first 10 days, but when we reached a total depth of 183 ft. labor troubles stopped operations for over six months. Water accumulated in the shaft to 12 ft. from the collar, but when work was resumed and the water pumped out, half a dozen truck-loads of soil sufficed to make good the small depression at the surface, thus showing everything to be in good order.

The mud-hole was rather deep to be due to the river action alone, and no boulder or other hard object was detected when probing, so it was probably not a large pot-hole. It seems more likely that it was an old fumarole, of which there are many active examples in the adjoining thermal district of Rotorua. There have been no other mud-holes found when sinking shafts at Waihi.

W. McConachie and W. Johnson, mine-manager and shaft-engineer, respectively, were responsible for this work; and Matthew Paul, Inspector of Mines, approved of the methods taken to ensure safe working.

Comments. If the shaft had been 10 ft. farther south, the mud-hole would not have been found. It is evidently much better to put down several boreholes, one for the shaft-centre and one for each leg of the head-frame, than to trust to a trial-pit, even though the rock of the district outcrops only 20 ft. away. The observed dip of the rock at the bottom of the trial pit, about 15°, did not suggest anything unusual. If the shaft be completed in the future, piles will have to be driven into the ground under the north-western leg of the head-frame in order to ensure safe foundation.

This Notice Appeals

In the psychology of persuasion, the first principle is that a person is most interested in that which directly concerns himself, or in what comes within the range of his experience. This cleverly worded notice takes advantage of the above principle, making a direct appeal to the employee by subtly suggesting an empty pay-envelope. This notice is to be seen in the Anaconda plant, at Butte.

Crude gypsum mined in the United States in 1918 amounted to 2,056,462 short tons, a decrease of 639,764 tons, or 24% from the output of 1917, according to R. W. Stone, of the U. S. Geological Survey. The decrease was due to the reduction in building operations throughout the country required by the local and national Governments. New York led with an output of 606,268 tons, followed by Iowa with 461,864 tons, Michigan with 375,803 tons, Texas with 257,328 tons, and California with 30,552 tons. The decrease in production was least in New York, where the output fell off only 12%; in Oklahoma, Michigan, and Ohio, the decrease was 20 to 26%, or about the average for the country. Texas suffered the greatest reduction in output, or about 39%. Utah was the only State that produced more gypsum in 1918 than in 1917.

REVIEW OF MINING

KINGMAN, ARIZONA

RECENT DEVELOPMENTS IN MOHAVE COUNTY

The Standard Minerals Co., operating a molybdenum property 24 miles east of Kingman, has opened a rich orebody in the Standard claim. The value across 30 inches of vein averaged $80 gold and 325 oz. silver per ton. A contract to sink to the 100 ft. level has been let and the work is under way. The company is operating a 40-ton flotation plant on the molybdenite-copper ore.

The Hackberry mill, at Hackberry, under the management of T. D. Walsh, is crushing 90 tons in 12 hours and making a high-grade concentrate. This is one of the first successful oil-flotation mills on lead-zinc ores in Mohave county. The lead and zinc products are high enough to meet smelter conditions, the lead carrying close to 200 oz. of silver. The mine stopes are being opened and will soon be able to meet the full requirements of the mill, when three shifts will be operated.

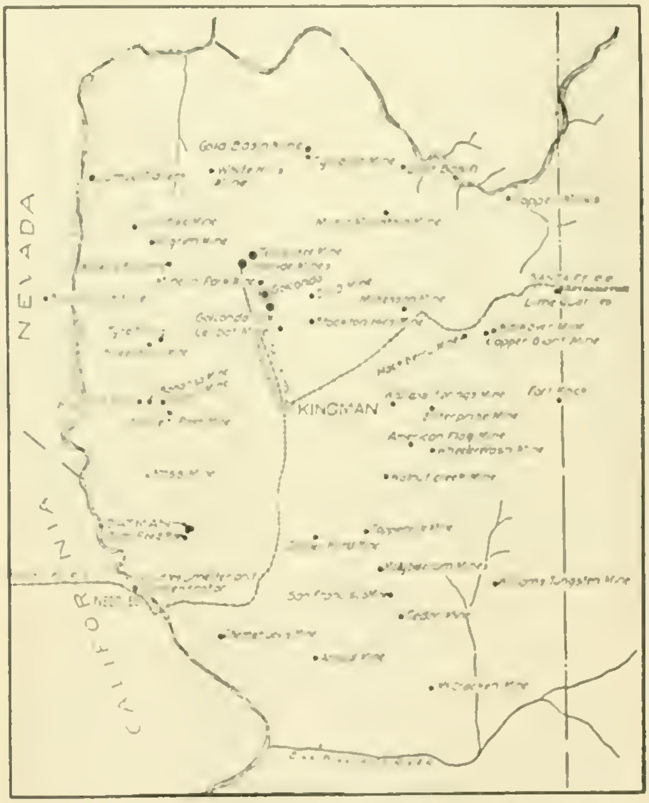
The Dorothy mine at Chloride is being equipped with a hoisting plant and other machinery, and the shaft sunk to the 300-ft. level. A tunnel has entered the Dorothy vein 125 ft. and a winze was sunk in 6 ft. of ore, which returned $40 net per ton in car lots. Water stopped sinking, a raise was driven to the surface, and a working shaft timbered. Sinking is under way.

The projected tunnel that is to serve the mines of Stockton hill, 11 miles north of Kingman, is soon to be in operation, Pittsburgh, Pennsylvania, people having completed the financing of the Arizona Butte company. The tunnel is to have a length of 10,000 ft., and will cut the vein near the summit of the Cerbat range at a depth of 1500 ft. Many of the important veins of that area will be cut at 1000 ft., and the whole mineralized area drained. A big vein—the Prince George—will be followed most of the length of the tunnel. The veins that will be cut by the tunnel have been heavy silver-lead producers for years.

The first mill-run by the Arizona Molybdenum Co., in the Cedar district, which recently put in new K & K machines, is reported to be a success. The new machines are making a good separation of the copper and molybdenite, the copper concentrate being clean and the molybdenite being rather free of copper and gangue.

The Twins mine, owned by the Daisell Mining Co., has at last picked up the vein beyond the fault on the 150-ft. level, and is now driving in 6 ft. of heavy sulphide ore. The vein faulted at the 80-ft. level, and although considerable effort was made to pick it up again failure has resulted. The shaft was carried to 300 ft., but no vein was found. The company now intends to start a cross-cut to cut the vein upon the lower level and proceed with the further exploration of the property. From the surface to the 80 ft. level shipping ore was taken out, the principal metal being lead, with gold and silver.

M. B. Dudley has just returned from Los Angeles, where he purchased a 50 hp. electric hoist, an 80-kw. motor and a large compressor for the Rural mine, at Mineral Park, which he and New York associates recently purchased. The machinery will be delivered immediately, and power is soon to be connected with the mine. A 100-ton mill is to be erected at once. It is estimated that there is sufficient ore on dumps of the Rural and Buckeye mines and in the stopes to keep a plant of that capacity in operation for the next year without further development. Streaks of rich silver ore have been found throughout the old workings.



SOME OF THE MINING DISTRICTS OF MOHAVE COUNTY, ARIZONA

A fine orebody has been found in the east drift of the Adams lode, at Oatman, after passing through a faulted zone. About 4 ft. of the 12-ft. vein assays nearly $40 in gold. A raise is also being driven in ore that carries as high as $90 per ton, although the orebody is narrower.

A cross-cut in the Tom Reed mine has passed through 6 ft of $15 ore in a new vein This has been driven from a level in old workings at a depth of 400 ft. Virgin ground runs from this level to the surface, the strike being made in new ground. Tom Reed is also driving on a new vein found at 400 ft. in Bald Eagle ground, which is said to carry good milling ore. This property is the largest in the Oatman district and has many important veins that have not been thoroughly prospected.

HOUGHTON, MICHIGAN

COPPER STOCKS ON HAND AT SMELTERS AND DOCKS.

Copper on hand at Lake Superior smelting plants early in June did not aggregate 30,000,000 lb. Some of the mines have small quantities stored in New York warehouses, but practically none abroad. The total on hand is just one month's output of the Michigan mines, operating under normal conditions. Calumet & Hecla and subsidiaries have the largest amount, namely, 20,000,000 lb. This is at the plant at Hubbell and the Lake Superior Smelting Co.'s plant, a subsidiary, at Dollar Bay. This latter works was shut-down late in May, and all smelting hereafter will be done at Hubbell. A fair quantity of mass copper at Dollar Bay was re-shipped to Hubbell for reduction. Whether the Dollar Bay plant will be re-opened when conditions improve is not known now. Since the opening of navigation, shipments of metal have been heavy, and practically all of the copper has been sent out to fill urgent orders. There is practically no copper on the Copper Range docks at Houghton. The Michigan Smelting Co., which handles all of the Copper Range output, as well as the Mohawk, Wolverine, and other properties, has 4,000,000 lb. This is not embarrassing, although it is an accumulation that is not normal.

RENO, NEVADA

SAMPLING OF ORE SHIPMENTS AIDED IN NEVADA.

The State Ore Sampler, Francis Church Lincoln, has sent out copies of the State Ore Sampler Law, which superseded the State Assayer Law. The new regulations were approved March 27, 1919. The new law is broader in its scope than the old one, since it provides for the supervision of sampling of Nevada ores wherever they are purchased, and authorizes the Sampler to obtain rates for shippers, call for umpire assays, and fix reasonable charges. As ore producers, miners naturally wish to receive the greatest possible returns. The State Ore Sampler Department will be glad to assist in doing this by every legal means. It will advise concerning shipments free of charge; and will take charge of shipments at a reasonable rate—checking the weight, supervising the sampling, determining the moisture, assaying the pulp, calling for umpire when necessary, and mailing full reports. To secure this service it is only necessary to notify the State Ore Sampler at the State Mining Laboratory, Reno, Nevada, and to mark bills-of-lading "Care Nevada State Ore Sampler". At Hazen there is a minimum charge of $5 on small lots, and 25 cents per ton is charged on lots in excess of 20 tons. At the Selby Smelting Works and at the Nichols plant of the General Chemical Co., in California, there is a minimum rate of $7.50 on small lots and a charge of 25 cents per ton on lots in excess of 30 tons. At the Mammoth smelter in California and the Garfield and Murray smelters in Utah, the minimum rate is $6.25 on lots of less than 25 tons. Minimum rates at other points will be fixed as rapidly as possible, but at present rates at purchasing points not mentioned are actual costs of supervision for lots of less than 50 tons, and 25 cents per ton on lots of 50 tons or more. Special low rates may be made upon large lots to suit local conditions.

GOLD HILL, OREGON

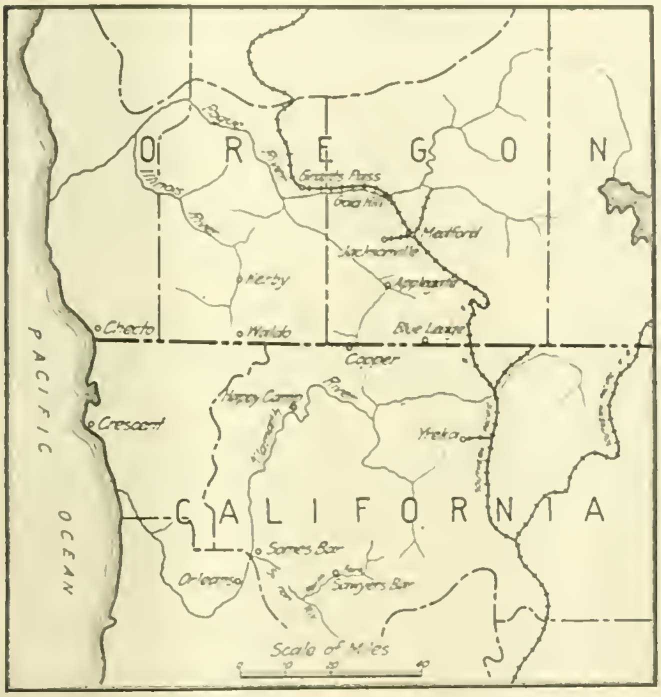
COPPER, QUICKSILVER, AND GOLD MINING, AND CONTEMPLATED EXTENSIONS; ALSO ROAD CONSTRUCTION.

Gold mining companies in this region that took up the extraction of chrome, copper, manganese, and mercury during the War, and expected to resume the mining of gold afterward, are now fully convinced that the scarcity and high prices of labor and machinery will cause a prolonged suspension of a general resumption of gold mining in this region and in northern California.

The only copper property operating at present in southern Oregon is the Blue Ledge group on the Oregon-California boundary in the upper Applegate district. Its weekly output is three cars of ore carrying over 12%. The wagon haul to shipping at Jacksonville is 35 miles, at a cost of $11 per ton. The Tacoma, Washington, smelter, which is treating the ore, recently had officials at the mine and propose to double the output by handling lower-grade ore.

The Rainier Mercury Co., of Tacoma, has been operating two 12-pipe furnaces on rich cinnabar, with a daily output of three flasks during the past two years from the Utah group of 35 claims, north of Gold Hill. The new organization, the War Eagle Mining Co., recently organized at Medford, and composed principally of local men, has taken the property over, doing some development and operating the present plant. They propose to erect a 500-ton furnace during the coming season to calcine lower-grade ore, and claim that they can produce mercury at $55 per flask at a profit.

The original old channel or bed of the ancient river, recently uncovered in the Esterly placer mine in the Waldo district, west of Gold Hill, is being successfully developed, operating in gravel carrying coarse gold. After passing through a barren zone on the bed-rock sluiced off years ago, a pit to the depth of 25 ft. has been piped below the level of the former workings, at a point between two benches of bedrock. This pit opens a bed of gravel entirely different in character from clay banks that were so profitable during the pa years. The depth of this gravel has not yet been termined, neither has any clean-up been made on which to show high gold content. Heretofore, the gold recovered at this mine has been fine and flour gold, and evenly distributed through the clay banks, which are from 10 to 40 ft. deep. This property, formerly known as the Logan mine, and the Simmons mine, has been worked at a large profit during the past 50 years, and consists of 4200 acres, practically all profitable placer ground. Water-right consists of 14,000 inches, and is supplied by a system of ditches 25 miles in length. It was purchased in 1916 at a cost of $140,000 by Seattle people, with George M. Esterly at the head as manager and superintendent, and has been yielding for some years $40,000 in gold dust and $10,000 in platinum annually. The lack of grade for the dumping of tailing led to the erection of a hydraulic elevator system, the residue being lifted 73 ft. by two elevators. With the opening of the new pit an additional elevator has been erected, making a total lift of 89 ft. above the pit. All the standard placer gold-saving devices are in use, but due to the fineness of the gold much is lost and carried over in the tailing. It is proposed to dispense with this system this coming season at a cost estimated from $40,000 to $50,000, by opening a race through a 700-ft. tunnel through serpentine to the west fork of the Illinois river. The daily capacity of the mine at present is 1000 cu. yd., at an average cost of 6 cents per yard, but with the new system the capacity will be greatly increased, with a reduction of operating cost.



CALIFORNIA-OREGON BOUNDARY REGION

Yreka, California.—The San Francisco District Forester's office has notified the Yreka forest office of the awarding of two contracts for road construction on the proposed Happy Camp-Klamath River road, the section of 15 miles near Happy Camp being let to W. A. Bechtel of San Francisco for $25,000. This still leaves 26 miles to Orleans unaccounted for. Nearly all of this road will be cut out of rocky mountain sides. Another contract for 7½ miles between Orleans and Somes Bar in Humboldt county has been let to William B. Arndt, of San Francisco, for $150,000. The contracts for the construction of the balance of the road between Orleans and Happy Camp are expected to be let later in the season. All this road construction is being undertaken by the Department of Agriculture, Forestry Division.

GRASS VALLEY, CALIFORNIA

LABOR TROUBLES SUSPEND OPERATIONS.

At the time of changing shifts on June 13 a delegation from each department waited upon A. B. Foote, manager of the North Star mine, and demanded a 50-cent increase in pay per shift for each man underground. This was refused, and every man, 120 in all, left the property. The present scale is $4 for machine-men and $3.50 for shovelers, with bonuses for extra work. The causes are conjectured at this time. One report is that men received from the outside are getting more pay than the old hands, and another that such men receive their fare if they remain a month. The company denies the first charge, but a short time ago when men were leaving for Divide, Nevada, in such numbers as to seriously affect operations, the company advertised that the fare of men coming from the outside and remaining a month would be guaranteed them in addition to the usual mine wage. Everybody knew of that, and no dissatisfaction has openly appeared because of such guarantee. The day shift followed the night men at the North Star mine, and all underground work ceased. The strike then spread to the Empire where the men quit in a body, without consulting the management. A mass-meeting was held on the afternoon of the 14th, presided over by J. B. Bennetts. The position was discussed and committees appointed to present demands upon the management of the Allison Ranch, Champion, Empire, North Star, Orleans, and Pennsylvania. These are the large properties operating at present. The gist of the argument was to the effect that the miners could not support their families on the wages now paid, due to the increasing cost of living. Some alleged that local merchants were 30% and upward over Sacramento prices. Surface men present were requested to join the movement, but there was not a single response. The sense of the meeting was that all top men should demand a raise of 50 cents. Committees were appointed to encourage these men in that direction. Mr. Foote, of the North Star, is insistent upon closing indefinitely rather than accede to the demand. He states that under present conditions the mine is about holding its own and has not paid a dividend since the outbreak of the War. [One is to be paid on June 28.] A strike pledge was signed and a relief fund discussed. It seems that the bonus system has not been popular—the men want a flat rate of a 50-cent raise.

THE MINING SUMMARY

ARIZONA

Ajo.—New Cornelia in May produced 1,866,000 lb. of copper, about half of normal.

Bisbee.—Calumet & Arizona pays 50 cents per share on June 26. This is equal to $321,231, and makes $1.50 ($963,693) for 1919, and $42,096,351 to date.

Calumet & Arizona in May produced 3,848,000 lb. of copper, compared with 4,768,000 lb. a year ago.

The Phelps Dodge properties in May yielded 8,355,900 lb. of copper, less than half of normal.

Clifton.—Arizona Copper Co. in May produced 2,400,000 lb. of copper, against 4,130,000 lb. a year ago.

Globe.—Old Dominion in May produced 2,564,000 lb. of copper, 700,000 lb. less than a year ago.

Jerome.—United Verde Copper Co. paid $1.50 per share to its 22 holders early in June. The amount was $450,000, making $900,000 for 1919 and $51,497,000 to date.

Operations are to be resumed at the Green Monster. The main shaft of the Silver Tip claim is to be unwatered and exploration carried on to develop the silver vein. The company is to sink a 200-ft. incline shaft on this claim.

Miami.—Inspiration Consolidated produced 6,200,000 lb. of copper in May, 5,000,000 lb. below capacity. Miami produced 4,989,580 lb., up to the average.

Oatman.—The United Eastern pays 7 cents per share on June 28. This is $95,410, making $517,940 for 1919 and $1,771,900 to date.

Driving on the 400-ft. level of the Bald Eagle claim of the Tom Reed mine has opened 6 ft. of gold ore said to average $15 per ton This vein is believed to be a new one. It is expected that ore from this section of the Tom Reed property will be going to the mill within a month.

Patagonia.—The Three R M. & M. Co. has gone into the hands of a receiver due to the depression in the copper market. The company owes $200,000 and had been working the property under bond and lease from R. R. Richardson.

Prescott.—R M. Merrill and Pacific Coast associates have acquired 560 acres of placer ground near Octave. Preliminary operations are now under way.

The property of the Swastika Mines Company, which has been working under lease, has been sold to the Swastika Silver & Copper Mining Co. The mine is to be equipped at once with a 50-ton mill and development is to continue. It is estimated that there is 70,000 tons of silver ore in the mine and on dumps.

Quartzsite.—The Meroquite Mining Co. started its Gold mill on May 28. A good deposit of high-grade free-milling ore was developed last winter.——The Ravina Scott mine has also opened a large quantity of high-grade gold ore, and the owners are arranging for a mill.——The Boyer Gold & Copper Co. has its machine-drills running and is opening stopes preparatory to shipping high-grade ore.——The Copper Chief shaft is down 600 ft. Driving on ore will soon begin.——The Pecotche lead and silver mine, 7 miles east of Quartzsite, has men sorting ore for shipment.——The Cully copper mine, south of this place, has the richest copper ore found recently. Assays return up to $60 gold, $57 silver, and 26% copper.

Ray.—The Half Moon Mining Co. has been formed by local people to operate 10 claims at Red Hill, 12 miles from Florence. Some work has been done there, opening some high-grade copper-carbonate ore.

The controlling interest in the Little Bobbie Mining Co. has been obtained by the Ray-Broken Hill Mining Co. by the purchase of the shares of W. J. Graham, president of the former. Development is now being carried on by the Ray-Broken Hill, and it is expected that work will be extended into its new holdings.

On June 30 Ray Consolidated company pays 50 cents per share, equal to $788,589. This is similar to the previous dividend.

CALIFORNIA

Grass Valley.—The North Star Mines Co. has resumed paying dividends. On June 28, No. 56, of 40 cents per share, amounting to $100,000, will be distributed. The total is now $5,537,040.

David Whildin has sold the East Eureka claim to the Idaho-Maryland Mines Co. for $11,000. The claim lies between the Old Eureka and Idaho mines. Litigation several years ago resulted in Whildin having been awarded a clear title.

Jackson.—In the 'Press' last week some notes were given about the Gwin mine, closed since 1908. The large sums paid in dividends were not mentioned, and it is now stated that the last operations were not confined to "quickly worked-out bunches of ore." According to the State Mining Bureau's county report, issued in 1915, "the ore-shoots of the main vein are of great length, varying in width from a few inches to 20 feet."

La Porte.—This old placer-mining centre was partly destroyed by fire on June 14. The damage was confined to the business part of town. Some historic records are said to have been burned. Those documents and plans held by Surveyor Hendel were of great value to the State, especially concerning the exposed and buried gravel channels of Sierra county, and should be secured by the State Mining Bureau, as there is much gravel yet available.

Plymouth.—The Plymouth Consolidated during April treated 10,700 tons of ore for $60,000 of gold. The net profit was $14,000. On the 2450-ft. level, the raise at 274 ft. north was advanced 52 ft. to a total of 75 ft. The average value across 42 in. was $8.80 per ton. At 2600 ft. the shaft-station has been enlarged for an electric sinking-hoist. The report of the company for 1918 is to hand and contains the following:

After providing for depreciation there remained a net profit of $139,000. Adding the previous balance there was available $225,000. Two dividends absorbed $115,000. The balance carried to 1919 was $82,000. Current assets amount to $240,000, including $86,000 in cash; and current liabilities are $81,000. Development amounted to 6681 ft., on 12 levels to a depth of 2600 ft. Work on the north shoot at 2450 and 2600 ft. opened good ore, also south of the shaft at 1400 and 1500 ft. Reserves more than kept pace with extraction of ore. The mill treated 125,300 tons of $6.19 ore, almost the same as in 1918. The yield was 33,382 oz. of gold and 8530 oz. of silver, 68% of the gold being saved by amalgamation and 32% by concentration. The extraction was 88.92%. Costs were 50 cents per ton for development, $2.22 for mining, 48 cents for milling, 28 cents for bullion and concentrate charges, and 34 cents for general expenses, a total of $3.82 per ton. J. F. Parks is superintendent.

Nevada City.—After an investigation by C. A. Logan—deputy in charge of the branch of the State Mining Bureau at Auburn—William Macguire located a deposit of barite at Liberty hill, a few miles east of Nevada City, and immediately put several men to determine its extent and quality. The outcrop is immense—60 ft. high and several hundred feet long. The deposit is six miles from Dutch Flat on the railroad, and should the quality meet market requirements, a local plant will be erected.

A suit of importace is being tried in the Superior Court, without a jury, involving title to valuable mining claims near Washington, 20 miles east of Nevada City. The plaintiff, Miss E. E. Hoeft, brought the action against Frank T. Smith and others to quiet title to the Lucky Strike and Lucky Strike Extension. Plaintiff acquired her title through purchase on a gold location; defendants located for gold and asbestos, claiming that plaintiff failed to perform the necessary assessment labor for 1916. At the same time defendants' locations are in doubt because of vagueness of description and uncertainty of position. The case has been complicated further from the fact that defendants bonded their locations, at the same time attempting to cover plaintiff's claims, to the Sierra Asbestos Co. of Oakland. The latter erected a mill and treated ore last year from an open-cut, and made one shipment of short fibre asbestos. The case is being contested bitterly. Defendants are each represented by counsel, five in all, with Thomas H. Dozier of San Francisco as senior counsel, while L. P. Larue and W. B. White of Grass Valley represent plaintiff's interest.

Melones.—The Carson Hill Gold Mining Co., directed by W. J. Loring, has been extracting some rich ore from its bottom level—675 ft. Some of the lots were as follows: 59 tons averaging $249 per ton, 182 tons at $87, 73 tons at $70, 292 tons at $34, and 530 tons at $46.52. The profit for June will probably be $70,000. The shaft is being sunk another 200 ft., and by August the 875-ft. level will be opened.

Sawyer's Bar.—The following notes will show what is being done in this part of Siskiyou county:

The Sauerkraut placer mine on Salmon river is being worked again with five men, opening old drifts and sawing lumber to build a new flume. Work will be carried on throughout the season. Charles Lilly is in charge.

The Nordhammer hydraulic claim is being tested by A. L. Fulton of Oakland, who is part owner. There are three men at work. If the tests are satisfactory a new flume will be built.

The Northern California Exploration Co., a Californian corporation, has taken over the Gilta and Knownothing quartz properties, and will prospect them thoroughly with diamond-drills. A driller and 5 men are there now. W. R. Beal is superintendent.

The Forks of the Salmon River Mining Co. is operating. This is the largest hydraulic mine to operate all the year around in America now, since Lagrange in Trinity county was closed. An 18-in. elevator has been erected. Three No. 5 giants, with 6-in. nozzles, under a 235-ft. head in the pit, are working. The main flume carries 3000 inches of water, and the lower flume about 2000 inches. A water-power derrick handles rocks up to 7 tons. During May, 30,000 cu. yd. of gravel was put through the main sluice. Nine men working. John D. Hubbard of San Francisco is in charge.

Trinity Center.—The new boat of the Estabrook Gold Dredging Co., the largest wooden dredge in the world, it is claimed, started work on June 9. The hull is 152 ft. long by 68 ft. wide. The craft cost over $600,000. The buckets have a capacity of 20 cu. ft., there being 80 of them. One million feet of lumber, cut near the site, was used in construction. The hull was launched on November 26. The machinery was made in Milwaukee. The freight bill to Redding was $50,000, and it cost as much more to haul the material by auto-trucks over the mountain roads for 54 miles to Trinity Center. The point of the spud weighs 8½ tons, and the spud complete 60 tons. The boat draws 10 ft. of water. The company has several hundred acres of ground along Trinity river. The new dredge supplants the old one built by the Alta Bert company, which was in operation for several years, or until it sank.

COLORADO

Boulder.—None of the tungsten mines or the 11 concentrating plants erected in this district during 1916 are in operation. The only work is that of the Tungsten Products Co.'s refinery, making ferro-tungsten, and the Black Metals refinery, making tungstic acid. It is said that the acid is produced from ore imported from China, two carloads arriving last week.

Cripple Creek.—The Cresson's profit in May was only $55,000, while monthly dividends of 10 cents per share amount to $122,000. Ore-reserves are reported as containing large profits.

The Colorado Springs & Cripple Creek railroad—the Short Line—will probably resume running shortly. The road is in the hands of the bondholders.

The Portland company has announced a new schedule of treatment charges on low-grade mine and dump ores, as follows: Up to $3 value, $2.00 per ton; $3.50 at $2.25; $4 at $2.50; $4.50 at $2.65; $5 at $2.75 per ton.

Gateway.—A shortage of men continues in the Paradox valley. The importance of the new mining field is being recognized, and by the end of the year there will be improved transportation facilities, as the roads from Telluride will be repaired, and there is a survey under way from Gateway to the lower Paradox, with excellent prospects for its construction.

At the new mill of the Primos Chemical Co. construction is proceeding rapidly; the concrete foundations are laid, and the iron and steel for the structure is arriving, so the outlook is favorable for early completion.

The Radium Company of Colorado is confining operations to development, owing to the fact that there is a large quantity of ore on hand ready for shipment.

Georgetown.—The Georgetown Tunnel Transportation Co., C. G. Breitenbach president, is to build a mill near the mouth of the tunnel.

Leadville.—Before the end of August a number of idle properties will be at work. The Ibex and Garbutt are gradually getting back to normal production, while the Penrose and Dold properties are at full capacity. The Iron Silver company has moved pumps and water-columns from the Mikado to the Pyrenees shaft. Silver properties in the Sugar Loaf district are being worked by lessees and companies.

IDAHO

Bonners Ferry.—The Idaho Continental Mining Co., with properties at Klockmann, will resume operations at once, according to A. Klockmann, president and general manager. He stated that he would start with at least 100 men. Two shifts will be worked in the mine and three in the mill. Men are now overhauling the machinery.

Burke.—The Hecla Mining Co. is now employing 500 men at its mine here and the mill at Gem.

Mullan.—The National Copper company made a profit of $20,000 during May, from 7000 tons of ore. The new shoot on the 800-ft. level is responsible for this sum, which is a large increase. The orebody has widened from 4 in. to 25 ft. The shoot is 200 ft. long. Concentrate contains 16% copper and 47 oz. of silver per ton.

Wallace.—Since wages in the Coeur d'Alene were cut by $1 per day, and recently advanced by 50 cents, the national labor unions have been trying to unionize the men of this region. The local secretary, M. P. Villeneuve, at Burke, of the Coeur d'Alene District Miners' Union No. 14, International Union of Mine, Mill & Smelter Workers, formerly the Western Federation of Miners, circularized the managements of all the mines, asking them to confer on establishing an 8-hour day in all departments, an increase of 50 cents per day, and an agreement to form a basis of relationship between employers and employees, such as can be arranged in friendly conference. To this request the companies replied not to the Union, but "To all employees of the Coeur d'Alene mines." They stated that the 8-hour law has been adhered to strictly, that the present scale of wages is similar to that at Butte and higher than paid in California and Utah, and that the third proposal is recognition of the Union, which is refused on the grounds that the mines are on the open-shop basis. The reply is signed by the Bunker Hill & Sullivan, Caledonia, Consolidated Interstate-Callahan, Federal, Gold Hunter, Hecla, Hercules, Sierra Nevada, and Tamarack companies.

ILLINOIS

In Bulletin 169, Law Serial 15, J. W. Thompson of the U. S. Bureau of Mines has completed the Illinois mining statutes annotated, including all the mining laws of that State. Some of the principal subjects treated are the Engineering Department of the University at Urbana, the Geological Survey, mine fires, inspectors, mineral lands, miners wages, liens, and change-houses, corporations, mining rights, shot-firers, coal, and compensation acts.

MICHIGAN

Houghton.—Quincy pays $1 per share on June 30. This is equal to $150,000 and makes $300,000 for 1919. The company has purchased 125 acres of land from the Hancock for $235,000. In 1915 Quincy bought 80 acres from Hancock.

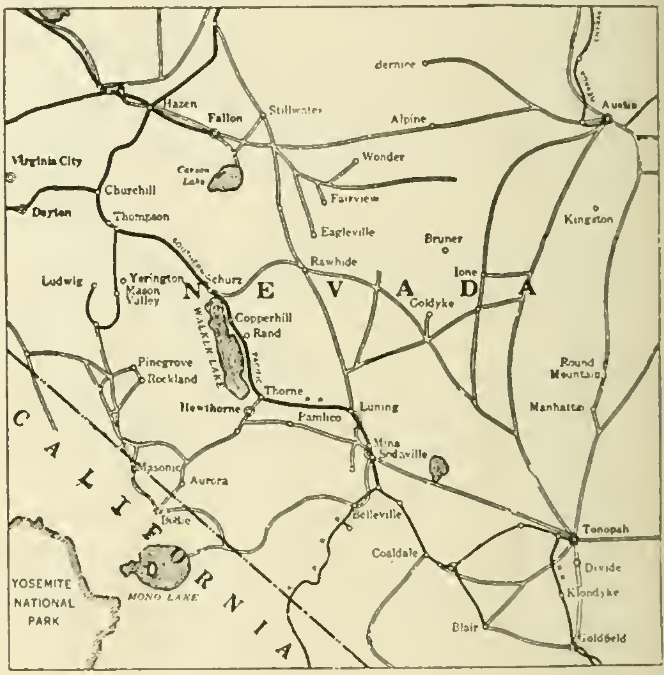
NEVADA

Ely.—Nevada Consolidated pays 37½ cents per share on June 30. This is equal to $749,796, and is the same as paid three months ago.

Goldfield.—The Original Klondyke, consisting of 200 acres in the Klondyke district, north of Goldfield, has been sold by Harry McNamara to the Original Klondyke Divide Mining Co., financed by New York interests. McNamara retains a controlling interest. The sale was made by Tim Connolly and J. W. Dunfee of Goldfield. The Original is one of the oldest mines in southern Nevada, having been worked 25 years ago, when the ore was hauled to Sodaville. The company that has taken it over is to sink a 1000-ft. shaft. The vein has been developed for a distance of 3000 ft., and has been exposed on the surface for widths of from 2 to 20 ft. None of the shafts is over 200 ft. deep. Until 1913 the mine was worked by James Golden, who is reported to have shipped ore valued at $290,000 gross. On the death of Golden, in 1913, McNamara took over operation of the mine and, according to smelter records investigated when the sale was made, shipped 123 carloads of ore averaging $28 per ton.

Sale of the Parker and Lockhart shares in the Florence Goldfield has been consummated, according to a telegram received from L. E. Whicher, head of the New York syndicate that bought control of the mine. The closing of the sale was reported in March, but according to information reaching Goldfield, Whicher had difficulty in securing delivery of the Parker shares. When the definite closing of the deal was announced, it was also made public that the Goldfield Development Co. had secured a lease on the northern part of the Florence, where, according to Development company's officials, there is 500,000 tons of low-grade ore in the extension into Florence ground of the Combination vein. This, according to estimates of A. I. D'Arcy, general manager for the Development company, will provide the company with from 2,150,000 to 2,200,000 tons of ore for treatment in the Consolidated mill. The estimate includes ore in the Combination, January, and Red Top.

Mina.—More than a dozen companies have been incorporated on the strength of developments in the Simon lead mine, 23 miles east of this place, and efforts are being made to boom the district. Engineers familiar with local conditions state that treatment of the ore presents difficulties, and that shipments to custom smelters will bring penalties for the zinc content, which runs from 10 to 14%. It is officially stated that a process has been devised for separation of the zinc from the silver-lead-gold ore, followed by treatment of the material by flotation at the Simon. Freight from the Simon to Mina costs $6 per ton.



MAP OF CENTRAL NEVADA

The cross-cut on the 400-ft. level of the Simon mine has penetrated the orebody for a width of 145 ft. The last 10 ft. is said to assay 34 oz. silver, 38% lead, and 24% zinc. An electric power-line is to be extended to the property from Mina.

Pioche.—Lincoln county produced 104,146 tons of ore valued at $1,123,488 during 1918, according to tax statements filed here. This is a decrease of 40,850 tons, mostly due to troubles on the railway from the Prince mine.

Round Mountain.—The Fairview Round Mountain Mines Co., managed by Gibson Berry, with E. Michal as mill superintendent, and R. J. Ledwick as mine superintendent, made an operating profit of $115,986 during 1918. Two dividends of 1 cent per share each absorbed $19,049. Development amounted to 1546 ft. at $9.04 per foot. The mine is opened to a depth of 250 ft., and the general outlook is good. The mill treated 8808 tons of $21.79 ore, of which 93.1% was extracted. Costs totaled $7.164 per ton. On June 25 the company distributes 2 cents per share, amounting to $19,049.

MEXICO

Chihuahua

Parral.—Telegraphic advice from El Paso, Texas, on June 17, stated that the American Smelting & Refining Co. had ordered its American employees to leave Parral and outlying districts of this State and go to the border immediately. The Cusi Mining Co. also ordered its men to go to the border from Cusihuiriachic.

NEW MEXICO

Hanover.—The Republic Mining & Milling Co. last year made a net profit of $51,911. Current assets were $44,681, and liabilities $7594. New work amounted to 616 ft., making a total of 1586 ft. An estimate of ore-reserves gives 50,000 tons, averaging 20% zinc. Fully 25,000 tons should be exposed this year. When finances permit, a 50-ton mill is to be erected. A water-supply has yet to be found. Shipments during 1918 were 2925 tons, realizing $108,868.

Santa Rita.—Chino Copper Co. pays 75 cents per share on June 30. This amounts to $652,485, and is similar to that of the previous quarter.

Tyrone.—The Burro Mountain of Phelps Dodge Corporation is to suspend operations, according to an announcement made at Bisbee on June 6 from the office of A. T. Thomson, assistant to the president of the Corporation. At the present time only tests on concentrates are being made at Tyrone. When these have been completed the mill is to be closed until such time as it is determined the copper market justifies a resumption. Development will continue.

UTAH

The State Board of Equalization at Salt Lake City has calculated the assessed valuation of all mines in Utah at just under $100,000,000. This is an increase of $54,000,000, fixed under the old law.

Bingham.—Utah Copper Co. pays $1.50 per share, equal to $2,436,735. Three months ago the same distribution was made.

Tintic.—The Tintic Standard pays 8 cents per share, $93,976, on June 27. This makes $187,952 for 1919 and $588,386 to date. The daily output is 150 tons, netting $30 per ton. E. J. Raddatz is general manager.

CANADA

Ontario

Cobalt.—The McKinley-Darragh-Savage paid 3%, $67,428, on June 7, making $202,284 for the current year, and $5,551,879 to date.

The Nipissing pays 50 cents per share on June 21. This is equal to $600,000, and makes $1,200,000 for 1919 and $20,340,000 to date.

It is stated that the Gillies Limit, described by Willet G. Miller in the 'Press' of June 7, will not be thrown open for prospecting this year. The reason for this is that the Government wishes to allow the lumbermen to remove what timber is left standing before miners are given permission to locate claims.

Porcupine.—The West Dome mine, closed since the disastrous forest fire of July 11, 1911, whereby 25 people taking refuge in the shaft were asphyxiated, is to be re-opened.

Yukon

Whitehorse.—The first steamers for Dawson and Fairbanks left here on June 9.

PERSONAL

Note The Editor invites members of the profession to send particulars of their work and appointments The information is interesting to our readers.

Herbert H. Roe has gone to Boston

Walter Hovey Hill is opening up a silver mine at Pearl, Idaho.

Arthur Jarman has arrived from New Zealand and expects to reside at Berkeley.

H. S. Munroe is manager for the Consolidated Coppermines Co. at Kimberly, Nevada.

Gelasio Caetani is serving as an Italian Food Administrator, working under Mr. Hoover.

Thomas N. Stanton has returned from Morococha, in Peru, and expects to go to Arizona.

James S. Wroth, of 42 Broadway, New York, has just returned from professional work in Portugal.

Percy R. Middleton is doing experimental work for the Chief Consolidated Mining Co., at Eureka, Utah.

Marshall D. Draper sails from New York for the Orient on July 1, where he will engage in exploration work.

Donald F. Irvin is making a professional journey to Bolivia and Peru. He is now at Antofagasta, in Chile.

Fred Searls, Lieutenant of Engineers in the A. E. F., has returned to San Francisco and resumed practice as mining geologist.

Francis L. Bosqui has gone from London to New York, where he will establish himself as metallurgical engineer at 90 West street.

Lionel Lindsay, at one time News Editor on the M. & S. P., is an attaché on the Military Section of the British Delegation at Paris.

John L. Sihoney and **K. T. Parks**, of the Federal Bureau of Mines, spent several days in the Grass Valley district during the past week.

Rensselaer Toll, who has been appointed War Minerals Relief engineer, is investigating claims in Santa Clara county, California.

Horace F. Lunt has been appointed Commissioner of Mines for the State of Colorado, in succession to **Fred Carroll**, who resigned.

H. C. Carlisle has been appointed general superintendent for the Nevada Wonder Mining Co., at Wonder, Nevada, to succeed **E. E. Carpenter**, who resigned.

R. G. Hall, resident manager for the Burma Mines Limited, has left Namtu, Northern Shan States, Burma, for London, on business for the corporation.

John D. Hubbard, recently Captain in the Army, is superintendent of the Forks of Salmon River Mining Co., near Sawyer's Bar, Siskiyou county, California.

The Deputy Minister of Mines, **R. T. Tolmie**, of British Columbia, who has been ill for some time, has been granted an extended sick-leave, and **W. Fleet Robertson**, the Provincial Mineralogist, by an order-in-council, has been made acting deputy.

W. A. Sloan and **E. Leland** have taken over the assaying and engineering office of Kempton & O'Neill at Nogales, Arizona. Both have been connected with the Shannon Copper Co., the one as mining engineer and the other as chemist for 8 and 10 years, respectively.

C. M. Eye, for many years superintendent in charge of the mines of the Benguet Consolidated Mining Co., Benguet, Philippine Islands, is returning to the United States in July. He expects to be in or near San Francisco, and mail may be addressed care of Wells Fargo Nevada National Bank.

THE METAL MARKET

METAL PRICES

San Francisco, June 17

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8.50
Copper, electrolytic, cents per pound	17.75
Lead, pig, cents per pound	5.65—6.65
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce	$115
Quicksilver, per flask of 75 lb	$95
Spelter, cents per pound	8
Zinc-dust, cents per pound	10—12

EASTERN METAL MARKET

(By wire from New York)

June 17.—Copper is quiet but steady. Lead is active and strong. Spelter is quiet though firm.

COPPER

Prices of electrolytic in New York, in cents per pound.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May, 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

The American Smelting & Refining Co., the U. S. Smelting & Refining Co., and the Anaconda Copper Mining Co. are to form a silver export company to endeavor to alter the silver situation, particularly as regards price-fixing in Great Britain. These three companies in 1918 handled over 94,000,000 oz. of silver, equal to 55% of the world's ouput in that year.

On May 20 J. W. Rowe, U. S. vice-consul at Mexico City, cabled that a treasury circular published on the above dates announces that the silver bars may be exported from Mexico during June without an export license, and without the necessity of importing any percentage of gold in substitution.

Discussing silver on May 22, Samuel Montagu & Co. of London said that the restoration of freedom to the London market has been accompanied by a healthy return of business. Supplies have been plentiful, and have so far anticipated the Continental demand, which is surely though slowly being resumed. As a matter of fact, the markets in the neighboring Allied and neutral countries hardly yet realize the fact that London is quite prepared to supply raw material for industries and for coinage, which has been suspended during the period that export of silver from the United Kingdom was restricted, and the price officially regulated. The War Trade Department is giving the most cordial assistance in facilitating the provision of export licenses, which are granted freely. The abundance of supplies from America suggests that producers had laid in stocks for a rise, and this not being forthcoming and there being a good profit on the original stocking price, are realizing with some freedom. When this special source of supply is taken off the market and the Continent has waked up, prices may perhaps be more robust, and buyers for forward delivery, who have been lately in considerable evidence, would then be able to justify their purchases. The Shanghai exchange eased slightly to 5s.1½d. the tael, equal to 52¾d. ($1.04¾) per ounce standard (expenses of transmission excluded). There was the usual demand for the India Council allotments on the basis of 1s.8d. (40 cents) a rupee, the limit to which they were raised on May 13. It was officially stated on May 20 that 194,961,672 fine ounces had been delivered in India up to May 1 under the Pittman Act.

LEAD

Lead is quoted in cents per pound, New York delivery.

June	9.63	7.92	....	Dec.	7.84	8.49	....

Zinc ore at Joplin, Missouri, averaged $41 per ton last week, basis of 60% metal. The Tri-State output was 7737 tons of blende.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date					
May	20	82.00	June	3	95.00
"	27	92.00	"	10	92.00
			"	17	95.00

Monthly averages

	1917	1918	1919		1917	1918	1919

June	85.50	112.00	....	Dec.	117.42	115.00	....

The quicksilver market is bare of supplies and the demand is good. New York quotes $92 per flask; and London about £18 ($85). Exports during May amounted to 1230 flasks, chiefly to Hongkong and Japan. This is an increase of 105 flasks over March, and 869 over February.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

The Cassel Cyanide Co. of Glasgow, Scotland, paid a dividend of 6 pence (12 cents) per share, equal to £17,625 ($84,000), on June 2.

Eastern Metal Market

New York, June 11

All the markets except that of tin are more active and stronger, and the price tendency is upward

Antimony is steady and strong.

Copper buying has again developed heavily, resulting in advancing prices.

Lead is stronger in sympathy with copper

Tin is dead and devoid of interest.

Zinc demand has increased, and prices are advancing gradually.

ANTIMONY

The market is quiet but strong at 8.37½ to 8.50c., New York, duty paid, for Asiatic grades.

COPPER

The market continues to improve, and the tone is strong with the price tendency upward. In the last few days demand and buying has been renewed with vigor and purchases have been heavy, particularly for August delivery. Some producers are well sold up for August. The price advance has been gradual almost each day, until today electrolytic copper for early or June delivery is quoted at 17.50c., with July and August held and sold at 17.75 to 18c., New York. Demand for Lake copper is good, with quotations ranging from ⅛ to ¼c. above electrolytic, early delivery being quoted at 17.75c., New York. The heavy buying referred to has been largely for domestic account, and both wire-makers and brass-makers have been involved. It is believed that demand is equal to or in excess of present output, but not enough yet to liquidate present stocks.

IRON AND STEEL

There appears to be generally less expectation of a decline in steel prices, though the volume of new business and rate of production have undergone little change in June. The improvement noted three weeks ago has been maintained. Outstanding features are new manufacturing capacity in the Middle West, and repairs and new construction work planned by a number of steel companies. Heavy demand for alloy-steel has come from automobile makers.

LEAD

The strong copper market has had its effect on lead. Both demand and prices have firmed as a result. Some business has been done since last Friday, which is reported to have been of fair proportions. The market is today quoted at 5.25c., New York, or 5c., St. Louis, with nothing lower obtainable. The cheap lots around 5.15c., New York, said to be available last week, are found upon investigation to have been impossible to secure. The market tone is strong and healthy.

TIN

Another statement from George Armsby, chief in charge of tin, appeared yesterday. It showed that stocks of the allocated metal had declined to 1907 tons on June 9, from 1615 tons on the 1st. Nothing definite is yet known as to when restrictions will be removed. It is, however, now established that imports of tin from Canada will not be permitted until shipments from the Far East have arrived, thus preventing any undue advantage to those who have collected tin for storage in that country. Such a procedure will thus protect the present buyers of allocated metal as well as the American smelters. It is announced that freight-rates from the Pacific Coast on tin to Eastern points has been reduced from $1.25 to 75c. per 100 lb., effective May 29. The market is stale and stagnant. Buying for shipment from the East or from England when restrictions are removed has tapered off to nothing and prices for such shipments are nominal at 50 to 51c. The allocated metal is still held at 72.50c., New York, the fixed price.

ZINC

A much better inquiry than in some weeks has developed, which has resulted in some business, and the tone of the market is considerably better. Some feel that the final turn has come. Prime Western for early delivery is quoted at 6.30c., St. Louis, or 6.65c., New York, with July held at 6.35c., St. Louis, and 6.70c., New York. For still further positions producers are generally shy about committing themselves. The new demand has been mostly from brass makers and special interests.

ORES

Manganese-Iron Alloys: Domestic ferro is in better demand, and most re-sale material seems to have been absorbed. What little remains is higher at $110 to $115, delivered. Producers are asking $125, delivered, and the British alloy is quoted at $121, seaboard. Spiegel is quiet at $27 to $30, furnace, depending on the analyses and the delivery.

Molybdenum: No business has been reported. Quotations are nominally low, about 80 to 95c. per pound of MoS, in 90% concentrates, but inquiries are better and more encouraging.

Tungsten: The following bill by Charles H. Timberlake, Congressman from Colorado, according to the report of the American Mining Congress, has been referred to the Committee on Ways and Means (H. R. 2949):

"A bill to provide revenue for the Government and to promote the production of tungsten ores and manufactures thereof in the United States.

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that on and after the day following the passage of this Act there shall be levied, collected and paid upon the articles named herein when imported from any foreign country into the United States or into any of its possessions, except the Philippine Islands and the Island of Guam and Tutuila, the rates of duties which are herein prescribed, namely

"First crude tungsten, ores and concentrates, $10 per unit of tungsten trioxide therein contained, a unit being herein defined as 1% of tungstic acid in a short ton of 2000 pounds.

"Second ferro-tungsten, powder, tungstic acid, calcium, tungsten steel salts, and compounds of tungsten, and all other manufactured materials containing tungsten, not especially provided for in this section, $1.25 per pound of tungsten contained therein.

"Sec. 2. That so much of any heretofore existing law or parts of law as may be inconsistent with this act is hereby repealed."

During the week the market for tungsten has been fairly active again. An excess of 100 tons of ore has changed hands, and while it shows a certain amount of business, the quantities ought to be much bigger in order to really make for higher prices. The sentiment, however, is much in favor of higher prices, as no material can be bought, according to advice received on June 9, from China at anywhere near the prices ruling heretofore. Bolivia also is reporting a much firmer market, and business under $10 for Bolivian scheelite and wolframite has been refused by the sellers. These prices refer only to the highest grade of ore.

Company Reports

WAIHI GOLD MINING CO.

Property: mine, mills, tramways, and power-plants in New Zealand.

Operating Officials: E. G. Banks, general superintendent; W. P. Gauvain, assistant; J. L. Gilmour, mine manager.

Financial Statement: gold and silver sold during 1918 realized £387,065 ($1,850,000), plus £27,773 ($129,000) for interest, etc. All operating expenditures totaled £215,564 ($1,030,000), leaving a profit of £199,274 ($949,000). From this, £42,851 ($201,000) was deducted for income-tax in New Zealand and London, and £16,724 ($76,000) for depreciation.

The market-value of investments at the end of the year was £538,125 ($2,580,000); also £49,845 ($235,000) cash at bankers, £30,400 ($144,000) for bullion in transit, and £55,357 ($264,000) stores on hand.

Dividends: four were paid—No. 99-102—of 24 cents per share each, making a total of £99,181 ($475,000). Since 1893 there has been distributed £4,974,446 ($23,875,000), and £551,314 ($2,640,000) paid as income-tax.

Development and Mining: new work covered 7366 ft., of which 3975 ft. was in 'suspense ore', that is, ore being extracted from arches and other workings. Reserves total about 610,000 tons. Eighty-five rock-drills were used. Ventilation was improved by more air-jets for induced currents. The electric plunger pumps lifted 413,492,100 gal. of water. A new turbine pump is being put in. The Cornish pump did not work. Two hoists are now driven by compressed air, generated by electric power. Electric heaters are used in the change-houses. Seventeen lodes contributed to the output of ore, the Martha accounting for 31% and the Empire 24%.

Milling and Production: the Victoria mill of 200 stamps and 11 tube-mills worked 298.6 days, an average of 120.4 stamps and 6.89 tube-mills running. They averaged 5.255 tons per stamp-day. The tonnage crushed was 188,998, assaying $7.50 gold and 2.75 oz. silver per ton. The proportions of ore-pulp treated were 21.77% as sand, 76.81% as slime, and 1.42% as concentrate, and the total extracted value was 91.7%. On the concentrate the extraction was 98.1%. During five years the extraction on the ore averaged 91.2%. The electrolytic refinery treated 561,348 oz. of doré bullion. The output since 1890 is valued at £12,265,771 ($58,870,000).

The hydro-electric plant, 51 miles from the mine, operated without trouble, and generated 17,107,550 units. The pressure is 50,000 and 11,000 volts.

Costs, including all office charges, totaled £1 2s.10d. ($5.48) per ton.

ALASKA JUNEAU GOLD MINING CO.

Property: mines and works near Juneau, Alaska.

Operating Officials: P. R. Bradley, general superintendent; John Richards, mine superintendent.

Financial Statement: the revenue during 1918 totaled $460,323, from gold bullion and concentrate. Operations cost $785,823, including $71,547 for interest and $26,920 for damages by storm. On April 1, 1919, the company's indebtedness, less cash assets totaled $1,580,000, which includes $943,000 of bonds sold of the new $3,500,000 issue. There has been spent to date $1,552,945 on mine development and $2,945,856 on construction and equipment.

Development: new work amounted to 5501 ft., mostly on No. 3 and 4 levels, preparing No. 410 stope. The assay-value of all development and preparatory mining work 'muck' samples (6921) taken between January 1913 and December 1918 averaged $1.041 per ton. Including 409 moiled samples taken since 1912 the average becomes $1.075.

Milling and Production: an endeavor was made to force the mill to its rated capacity during January and February, but the best daily average was 3832 tons, less than half of that expected. As wholesale mining and treatment was unprofitable at that time, sorting of the ore was done in March, April, and May; but because the 400 stope produced a lower grade and sorting was on so small a scale, there was no resultant economic advantage, therefore this work was stopped. The daily average during these three months was 1828 tons of 70.5-cent ore. During the next five months, when better ore was available, milling was reduced to the quantity of this material that could be mined with the labor available. The average daily run was 747 tons of $1.414 ore. The 50-stamp mill was incorporated into the flow-sheet, doing the work of the ball-mills. The stamps produced a ¼-inch product, which went to the tube-mills. Many improvements were made during this period. In the last three months of the year, when the 410 stope was yielding more ore, 1094 tons of $1.08 ore was treated daily. On December 4 the mill resumed work with three shifts. Alterations to the plant are to cost $500,000; these are expected to bring the daily capacity to 8000 tons. During 1918 there was spent $104,675 on the new mill, $30,508 on the power-plant, and $10,806 on the stamp-mill.

The mill treated 574,285 tons of ore averaging 87.5 cents per ton. Of this, 51.89 cents was recovered by amalgamation and 16.82 cents in galena concentrates. From 1914 to 1918, inclusive, the mill treated 1,666,740 tons of ore averaging 98.44 cents per ton. Operations last year cost $1.1329 per ton.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING CO.

Property: lead-silver mines, mills, and smelter in the Coeur d'Alene, Idaho.

Operating Officials: Stanly A. Easton, manager; William McDougal, mine superintendent; R. S. Handy, mill superintendent; M. H. Sullivan, smelter superintendent; R. A. Brockman, chief engineer; W. C. Clark, electrical engineer; E. P. Dudley, constructing engineer; F. P. Porter, master mechanic; C. W. Simmons, purchasing agent.

Financial Statement: the revenue during 1918 totaled $6,969,555, of which $6,128,667 was from metal sold, and $567,238 from the Caledonia and Sierra Nevada companies' dividends. Operations cost $3,769,138, which left a profit of $3,200,417.

Dividends: $1,553,250 was distributed, compared with $2,043,750 in 1917, bringing the total to $22,086,750.

Development and Mining: exploration consisted of 1740 ft. of drifts and cross-cuts, costing $13.739 per foot. The shortage of labor was especially noticeable in the second half of the year. Development on No. 15, or bottom level, was particularly successful, while the physical condition of the mines was fully maintained. Ore-reserves consist of 4,210,111 tons in the Bunker Hill, 135,479 tons in the Sullivan, and 16,434 tons in the Stemwinder. Stoping cost $1.582 per ton, and all underground work $2.385 per ton. Tramming by electric locomotive cost 7.8 cents, an increase of 2 cents; hoisting 8.1 cents, against 5.6 cents; and pumping 9.7 cents, more than double that in 1917.

Milling and Production: the mills concentrated 389,027 tons of ore, averaging 10.2234% lead and 3.8751 oz. silver per ton. The smelter produced 67,125,717 lb. of lead and 1,191,908 oz. of silver. The total cost of milling was 71.2 cents per ton, a gain of 11.2 cents. Since 1886, the output has been 8,275,913 tons of ore, valued at $86,341,659. Net smelter returns were $50,925,287, of which $28,771,132 was profit, plus $4,105,624 from other sources.

Book Reviews

Pumping Machinery. The history, design, construction, and operation of various forms of pumps. Second edition, revised. By A. M. Greene, Jr. Pp. 703, ill., index. John Wiley & Sons, Inc., New York, 1919. For sale by 'Mining and Scientific Press'. Price, $4.

Pumps and pumping machinery exported from the United States during February 1919 were valued at $711,450. During 1918 the total was $6,008,000. This machinery went to all parts of the world to be used in mining, oil, treatment works, and agriculture. The subject is one of great importance. In the book before us, which may be said to cover steam pumps, particularly, the first 130 pages on the historical development of pumps, from the time of the Egyptians to the present, will be found of value, as it shows the weakness of certain types and the improvements in design. A little more space might have been given to the Humphrey gas-pump, which has a big future in moving large volumes of water through low lifts. In the chapter on modern reciprocating pumps, consideration is given to boiler-feed pumps, fire pumps, a few well-known types of mine pumps, and deep-well pumps. A discussion of the dynamics of the water end of pumps, including the plunger and valves, occupies 70 pages; the design of pump parts 65 pages, and the dynamics of the steam end and steam-end details another 85 pages. Those chapters are for designing engineers. Among the high-duty pumps and water-works stations are shown a number of large installations, but one of the greatest of the high-duty types is that in Western Australia, where water is pumped 353 miles; this is not mentioned. Special pumping machinery, such as that for condensers, sewage, and hydraulic pressure, is described, including the ram. Injectors, pulsometers, and air-lifts come within the category of pumping apparatus, and are herein discussed, including calculations. Centrifugal pumps, especially those of the stage or turbine types for high lifts, are being used more and more, so the author devotes 130 pages to them. Many problems arise in their design and operation. The last chapter, of 19 pages, deals with mine pumps, but will be found rather short, as electric plunger pumps receive little attention and the 'shoe-string' centrifugal sinking type none at all. The millman will find nothing about acid, diaphragm, slime, or sand pumps. The descriptions and illustrations of modern pumps have been drawn largely from manufacturers' bulletins and from technical publications. It would seem that the book would be of value to designing engineers and to those who operate pumping plants of large units, more especially at water-works and in manufacturing industries. A good bibliography is available for all interested in pumping.

Applications of Electrolysis in Chemical Industry. By A. J. Hale. Pp. 148, ill., index. Longmans, Green & Co., London, 1918. For sale by 'Mining and Scientific Press'. Price, $2.50.

Electrolysis in the laboratory and refinery is expanding all the time, so the chemist and metallurgist must study what is published. This book will be found to contain a good deal of useful information. The introduction deals with the fundamentals of electrolysis. Suitable current may be generated by cells, thermopiles, dynamos, rotary-converters, and motor-generators. In giving costs of generating, British money might have been given in American also. The chapter on refining of metals includes American copper practice at Great Falls, and in New Jersey, lead at Trail, tin at Perth Amboy, and gold and silver at the Philadelphia Mint. It is said, under the heading of Cyanide Process, that the Siemens and Halske electrolytic process of recovering gold from solutions is much used in South Africa, this is not so now. Electrolysis is used in extracting metals from ores and chemicals, such as aluminum, calcium, sodium, and zinc. This treatment of copper and lead ores is not successful yet. Gases, such as hydrogen and oxygen, are used in large volume for welding, and they are made by electrolysis; the systems are explained. The electrolysis of alkali chlorides is an important industry, resulting in caustic soda, chlorine, bleaching liquor, hypochlorites, chlorates, and perchlorates, using aqueous solutions of sodium and potassium chloride. The various types of cells are fully considered. The last two chapters discuss the production of inorganic and organic compounds. Generally, a useful reference.

Irrigation Engineering. By Arthur P. Davis and Herbert M. Wilson. Pp. 617, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, $4.50.

Wilson's 'Irrigation Engineering' has been a standard treatise and book of reference for over 20 years. In this seventh edition, the co-operation of Mr. Davis has been enlisted, and the result has been a complete revision, with the addition of much new matter. The principal changes include a fuller treatment of subjects connected with the operation and management of irrigation systems, such as soils, plant-food, preparation of land for irrigation, duty of water, applying water to land, and maintenance of canals. The principal chapter-headings are Soils, Soil-Moisture, Plant-Food, Water Supply, Evaporation, Pumping for Irrigation, Irrigable Lands, Application of Water to the Land, Duty of Water, Measurement of Water, Drainage, Canals and Laterals, Canal Structures, Storage Reservoirs, Sedimentation of Reservoirs, Dams, Water Rights, Operation and Maintenance, Investigation of a Project, and Specifications. The final chapter contains some hydraulic tables. The book is well illustrated and will be useful to irrigation engineers, and to others engaged in the construction or operation of irrigation systems.

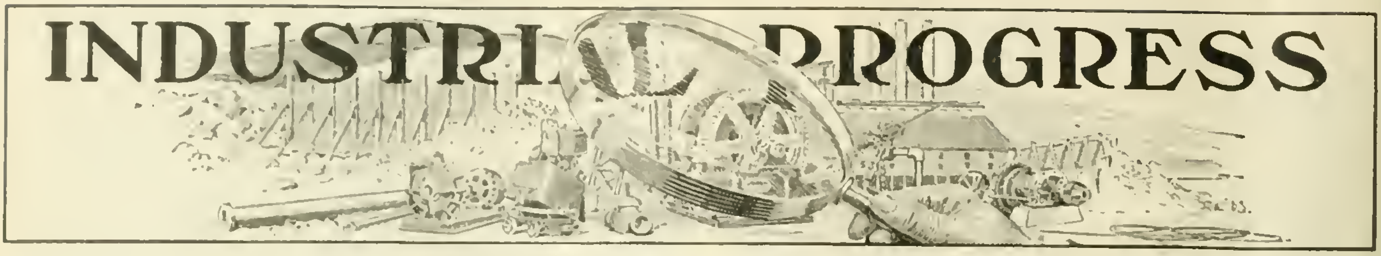
Punches and Dies. By Frank A. Stanley. Pp. 425, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, $4.

This is probably the most complete and up-to-date book on the subject that has appeared. The author has had much practical experience along these lines, and, at the same time, writes about his subject clearly. The first chapter is devoted to a general discussion of press-tools, and then dies of various kinds are taken up in detail, including dies for blanking, piercing, cutting-off, shaving, trimming, drawing, bending, forming, embossing, marking, riveting, swaging, and indexing, as well as combinations of two or more of these operations. The last few chapters are devoted to design, layout, construction, and heat treatment of dies. The book is well illustrated with both photographs and line-drawings. It will be of value to machinists, shop superintendents and foremen, and, in fact, to anyone interested in punch-and-die work.

Steam-Engine Troubles. By H. Hamkens. Pp. 267, ill., index. The Norman W. Henley Publishing Co., New York. For sale by 'Mining and Scientific Press'. Price, $2.50.

This is a practical book for the operating engineer written in non-technical language so that anyone with enough intelligence and experience to run a steam-engine can understand it. Chapters are devoted to the various parts of the steam-engine and the possible troubles that may develop, also to such special subjects as foundations, erecting, valve-setting, and operation. The book is illustrated with nearly 300 small line-drawings. It will be of value to anyone who runs a steam-engine or has one run for him.

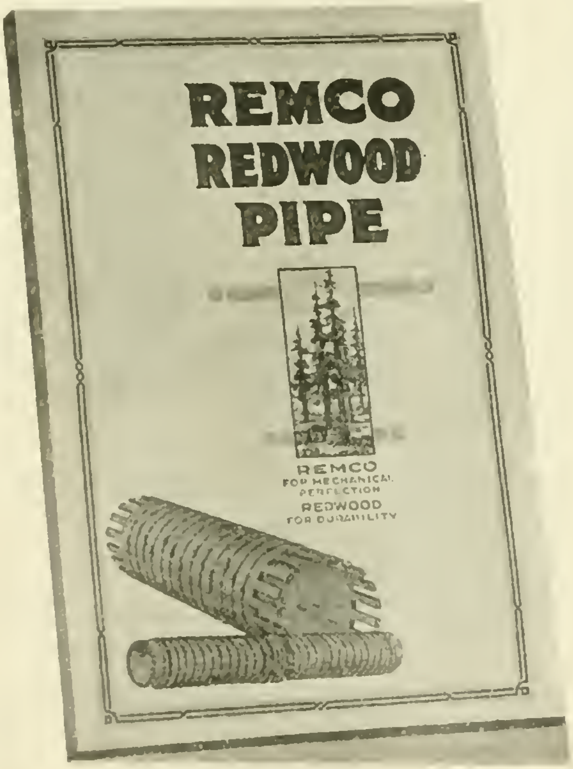
INDUSTRIAL PROGRESS



INFORMATION FURNISHED BY MANUFACTURERS

NEW REMCO CATALOGUE

The Redwood Manufacturers Co., 1611 Hobart building, San Francisco, has just issued a revised and up-to-date edition of its Remco redwood pipe catalog. This book is well printed and handsomely illustrated throughout. The various forms of Remco machine-banded and continuous-stave pipe are shown, and illustrations of typical installations are given. However, this book is more than a mere catalog of the company's product. It contains much valuable data of all sorts compiled from long experience. In fact, it is a complete engineering text-book on wood-pipe construction. Tables are given showing the allowable curvature in wood pipe-lines, relative capacities between wood and metal pipe, water-wheel requirements, pump speed and capacities, friction losses, flow-tables for various sizes of pipe, and other tables.



REMCO REDWOOD PIPE

REMCO FOR MECHANICAL PERFECTION
REDWOOD FOR DURABILITY

The Redwood Manufacturers Co., it will be remembered, supplied the United States government with over two million feet of Remco pipe, which was used at cantonments and Government work in this and foreign countries. Every foot of this pipe passed Government inspection, both at the factory and at destination, and not one foot was rejected. The same is true of Remco tanks, over 800 of which were furnished the Government.

Engineers will find this Remco redwood pipe catalog a handy adjunct to their library of technical information. It is not intended for free distribution except to men actively interested in pipe installations. The great expense necessary in its preparation prevents its being sent except where it can be used as intended. When writing for this catalog, note the work in which you are engaged and it will be sent without charge.

The Alaska Juneau Gold Mining Co., operating at Juneau, Alaska, with head offices at 1022 Crocker building, San Francisco, has sold $943,000 of its $3,500,000 bond issue, much of which is for improvements to the works. The annual report, just to hand, gives the following program for re-modeling:

Provision for sorting waste from Blake crusher feed, including stoneboats, gravity tramways, unloading-derricks, motors, track at west end of mill, 12-in. grizzlies over Blake crushers, water-supply for spraying, etc.

Substitution of the No. 9 by No. 6 gyratories.

Better speed adjustment of apron-feeders.

Construction of grizzlies at end of inclined conveyors.

Conversion of ball-mills into closed-circuit overflow type.

Installation of bucket-elevators for each two ball-mills.

Installation of double grizzlies at end of traveling conveyor over main ore-bins.

Installation of sorting and rejecting conveyor-belt over stamp-mill bin.

Installation of waste-disposal system for waste from stamp-mill picking-belt.

Construction of bins to receive and store pebbles from ball-mills at tube-mill floor.

Installation of shaking-screens in 50-stamp mill.

Extension of heating system into 50-stamp mill.

Re-locating mill and city salt-water pipe-line.

Purchase of additional ball-mill shells.

Extension of ball-mill crane and the working-floor.

Installation of additional salt-water pumping equipment.

Purchase of additional haulage equipment consisting of five 18-ton locomotives, 250 ten-ton cars, and construction of additional sidings.

Passenger elevator in mill.

Reconstruction of mill-roof covering.

Suitable barriers erected at critical points to prevent damage from possible storms and slides.

The estimated cost of the above is $500,000.

The St. Louis Daily 'Globe-Democrat' has been printing a series entitled 'Romances of St. Louis Business', and in the issue of May 18 is a full page under the heading of 'The Yellow Strand'. This refers to the **Broderick & Bascom Rope Co.** In 1875, John J. Broderick and J. D. Bascom started the business, and were the first wire-rope manufacturers west of the Alleghany mountains. Now the firm makes enough rope each month to tie together its works and warehouses at St. Louis, New York, and Seattle. The rope made is used for street railways, aerial tramways, shaft hoists, drilling wells, and many other purposes, and 'The Yellow Strand' is the trade mark for these products.

Rogers, Mayer & Ball, 42 Broadway, New York, regretfully announce the death of Leighton Stewart, of pneumonia, at the Mount Zion hospital, San Francisco, on May 21, 1919.

EDITORIAL

IN the third week of September the Exposition of Chemical Industries will serve to attract a succession of conventions to Chicago. The American Institute of Mining & Metallurgical Engineers will assemble on September 22 and the American Electrochemical Society on the 25th.

GERMANY'S importation of copper from this country in 1914 amounted to 311,107,962 pounds; in 1913 it was 280,930,086 pounds; and in 1912 it was 217,869,953 pounds, the value in 1912 being $29,741,716 and in 1914 no less than $45,960,362. It was the War and preparation for the War, not peaceful industry, that caused the Germans to buy copper so freely.

CARRANZA'S government is in a bad way when his northern commander, General Manuel Dieguez, has to warn the peaceable, law-abiding, and tax-paying residents in the Mormon settlements of western Chihuahua to leave their homes and cross into the United States for self-protection. The first function of government is to maintain order and by that test the *de facto* government of Mexico has failed.

HEARST'S recent attack on the President, by means of one of his bombastic signed editorials, is of good augury; as is Lord Northcliffe's offensive against the British Premier. When yellow journalism supports high authority it is time for honest citizens to become anxious. Both Mr. Wilson and Mr. George will be strengthened by the withdrawal of support from such quarters. The development of democracy suffers by the prostitution of journalism to the personal vanity of irresponsible publishers.

CLEMENCEAU, speaking as president of the Peace Conference to the German delegation, in final reply to their request for modification of the conditions, said: "In the view of the Allied and Associated Powers the war which began on August 1, 1914, was the greatest crime against humanity and freedom of the people that any nation calling itself civilized has ever consciously committed. . . . The conduct of Germany is almost unexampled in human history. The terrible responsibility which lies at her doors can be seen by the fact that not less than 7,000,000 dead lie buried in Europe, while more than 20,000,000 others carry upon them the evidence of wounds and suffering because Germany saw fit to gratify her lust for tyranny by resort to war." Before signing the treaty Germany was reminded thus that she was not only a defeated enemy but a frustrated criminal.

UNDER 'Discussion', Mr. William E. Greenawalt gives us an interesting letter on the hydrometallurgy of copper, with special reference to Mr. Percy R. Middleton's recent article on the treatment of flotation concentrate. He demurs to the assumption that the success of the electrolytic method of collecting the copper in low-grade ores at Ajo and at Chuquicamata is such as to furnish an assured basis of departure for metallurgists in other districts. There is reason in what he says. According to the annual report the Chuquicamata plant, of the Chile Copper Company, made a recovery of only 82% in 1918, while at the Ajo plant, of the New Cornelia Copper Company, for the year ending May 1917 the recovery was 74%, but since then it has been improved to nearly 80%. Not that Mr. Greenawalt would depreciate the work done either in Chile or in Arizona, for he has long been an advocate of the wet metallurgical treatment of such copper ores, as our readers will recall

AMONG the indiscretions provoked by the boom in the Divide district of Nevada we note a report by "an eminent mining engineer" whose geologic fantasies play havoc alike with the English language and the principles of a serious science. He avers that "the lithological structure of the Kickapah property is not difficult of fundamental determination." That remains to be proved. "The primary formation of the district essentially consists of a past carboniferous muscovite granite being the constituency of the core of Lone Mountain, some few thousand feet south and west of the property." The type-setter of the local newspaper from which we quote may have done his share in these "delirious trimmings" of geology, but even the proverbial printer's devil is not all to blame. Mr. Eminent Engineer finds a "silicified schistose zone" uplifted by "pyroxene diorite intrusives"; therefore he concludes that "these intrusives are the primary genesis of deep-seated hydrothermal solutions depositing present enriched mineralization of value." That last phrase is precious; it appears to be pseudomorphic after flapdoodle. It is curious how some otherwise sensible men love to talk in terms they do not understand and try hard to be impressive by using the abstract instead of the concrete, with the wholly mistaken idea that they are making a hit. They fool a very few people for a very short time, and expose their ignorance to those whose good opinion would help them most. Meanwhile the story goes that one boomster was telling another: "I was looking over the southern edge of Divide today." Whereupon the other said: "Did you see Carranza?"

BY the time this appears in print the Treaty of Peace will have been signed. The Germans tried to delay the capitulation, they bluffed and they whined, but, as was confidently expected, they threw up their hands at the last moment, not without suggesting that the signing did not bind them to carry out the contract in good faith. The War has ended in what oarsmen call a dirty finish; at the moment when the German government decided to accept the terms, the German crews on the surrendered battleships at Scapa Flow scuttled all the vessels, thereby breaking the conditions of the armistice to which the Germans had subscribed. The German admiral, Von Reuter, assumed responsibility for the act, stating: "I ordered the sinking in the belief that the Armistice was terminated and following the German naval tradition which knows no surrender." What a sense of humor! Of honor it is not worth while to speak. The fleet was surrendered and brought into captivity last November under its own steam and by its own crews; why did they not sink it when they decided to avoid the test of battle, instead of scuttling it when they were on their honor to behave themselves. The tradition of the German navy, of which the Admiral boasted, has gone down, scuttled forever, under the waters of infamy. What an end to the grand dreams of William II, Von Hindenburg, and Von Tirpitz!

FORMATION of a silver export combination, that is, of a group of silver-producing companies, is announced. This combination, legalized by the Webb Act, is to include the Anaconda Copper Mining Company, the American Smelting & Refining Company, and the United States Smelting, Refining & Mining Company, but it is to be open to all producers of silver, after the style of the similar organization created to control the exportation of copper. The New York 'Times' says that "an endeavor to control the world price is the objective behind plans for the formation of a silver export company by the three largest producers in this country. . . . More than half the world's supply of silver is produced in this country, but for more than thirty years the price has been regulated by an arbitrary fixing of values by a committee of three, the Silver Triumvirate, which holds forth in London." Well, we for one would like to see "a check to the domination of the silver market by the English committee" or by anybody else, including any one of the three smelting and refining companies mentioned above, but we confess to surprise in seeing the old yarn about the wicked three revamped in so good a paper as the New York 'Times'. If we remember correctly the bold bad men used to number four and they met every morning at 11 o'clock in order to fix the price of silver for the world. The fact is that the principal dealers in silver in London meet daily at the same hour in order to compare reports upon the dealings in silver and therefrom ascertain the average price for the day. The brokers in London no more fix the price of silver than our worthy contemporary in New York, or we in San Francisco, by reporting the average price of copper sales, "fix" the price of copper.

ON another page we reproduce an address on 'The English-Speaking Peoples', with the hope of promoting goodwill among some at least of the 547 millions living in the Britannic and American commonwealths, including a vast majority of men and women not of the same birth or ancestry. We hold with Theodore Roosevelt that the American has long ceased to be a cousin of the British and that the United States is not to be regarded any longer as an independent and overgrown colony of English origin. The American has become individual and the American people has developed its own entirely separate identity in the society of nations, but, while recognizing this fact clearly, we venture to plead for the establishment of cordial friendship between peoples speaking the same language and striving after the same ideals of fair play, justice, and government. Roosevelt himself, shortly before his death, wrote to a friend, saying: "I agree absolutely with you that this war has brought home to the great majority of thinking men in this country that we, the English-speaking peoples of the United States and the British Empire, possess both ideals and interests in common. We can best do our duty, as members of the family of nations, to maintain peace and justice throughout the world by first rendering it impossible that the peace between ourselves can ever be broken." The address on which we are commenting appeared in a bulletin of the Canadian Mining Institute, and, much to our surprise, elicited a long and indignant letter from a mining engineer, who charged the author with being grossly unfair to the part the Canadians had played in North American history and entirely misleading in his partisanship of the American point of view. Our correspondent exhibited an anti-American feeling that was, to say the least, disconcerting to the optimist and surprising to one fairly familiar with Canadian sentiment. Ancient prejudices have an unhappy way of lurking in unexpected corners. Our Canadian friend can be matched with those who still hark back to 1812 or those who on each January 30 place a wreath at the foot of the statue of Charles I. There are too many Bourbons in the world, forgetting nothing and learning nothing. Let the dead past bury its dead and let us face the present with unjaundiced mind, striving to widen our sympathy and enlarge our understanding with all those who speak the language of Shakespeare. That way lies the hope of an even wider mutuality of goodwill, which in time shall be extended to all the peoples of the earth. Whatever we may hope from Hague conventions or Paris conferences, it is certain that the best augury of general peace lies in the 3500 miles of unfortified frontier between Canada and the United States.

Industrial Co-operation

We take pleasure in publishing, in this issue, the text of an address delivered by Mr. W. R. Ingalls on this subject. We have given considerable space to this address because Mr. Ingalls was for 14 years and until three months ago the editor of our contemporary in New York, he is an honored member of the mining profession, and holds views on economic questions that are all the more interesting because they differ from our own. His utterance, moreover, suggests the awakening of the mining engineer to his duties as a citizen and the broader outlook that the exigencies of the War have forced upon men not usually politically minded. The dismal science of political economy has become quite an engaging study since the average citizen has begun to realize the impact of its application on his personal affairs; and the unending quarrel between capital and labor has become vital to the professional man now that he has learned to appreciate the danger of his position mid-way between the opposing forces. Mr. Ingalls launches forth by stating sundry fundamental principles and soon steers—he does not drift—into a glorification of capitalism and a reprobation of labor that leaves us cold. Even when he waxes furious and labels industrial democracy as "clap-trap" and "jargon," we feel no warmth of resentment against his reactionary sentiment because we believe that the mining profession is well able to think for itself and will accept the good thought in his address without being misdirected by a prejudice so undisguised. Mr. Ingalls appears to respond to his propinquity too much, the economic laws that he recapitulates as if they came from Mount Sinai are but the deductions of fallible men and some of them were predicated on conditions different from those now obtaining. The former editor of the 'Engineering and Mining Journal', and now its consulting editor, we understand, seems to show an adaptation to his environment when he charges the miners with "rapacity" because they tried to get a share of the profit accruing to the smelters from the high prices paid for metals during the War. On another occasion, it will be remembered, our contemporary charged the producers of chrome and manganese with profiteering under the disguise of patriotism, thereby wantonly insulting hundreds of worthy men whose motives were entitled to some respect. Now Mr. Ingalls seeks to chloroform the quicksilver industry of California, labeling it a "useless industry." He takes a good deal upon himself when he undertakes to do that. Even the fact that our domestic supply of mercury proved so eminently useful during the War would not deter him from shutting down the quicksilver mines of California, Nevada, and Texas, rather than give them the protection of a tariff as against imports from the mines in Spain. He would buy the cheaper Spanish quicksilver and store it as a reserve against the day when the next war interrupts overseas trade. Well, we think this is poor political economy. It seems to us wholly desirable that this country should be as nearly self-contained as possible, as little dependent on foreign sources of supply as our mineral resources will permit, and that it is worth while to prevent the extinction of a domestic industry that has served us so well in a great emergency and may serve again under like circumstances. We leave other controversial points in this interesting address, suggesting only that no great measure of industrial co-operation will be attained so long as the mental attitude of one side is expressed by the last five words of Mr. Ingalls' address "the authority of the super-capable few."

Mining Operations in the War

On another page we publish Sir Douglas Haig's farewell to the American Expeditionary Force and his special message to the engineers. General Pershing in his dispatches and his generals in their divisional orders have taken occasion more than once to express a similar appreciation of the Engineer Corps of the Army. It will be remembered also that on March 21, 1918, when the British Fifth Army at La Fere was suddenly overwhelmed by the concentrated attack of the Germans under Von der Marwitz, the advance of the Enemy was checked by the hasty organization of an instant line of defence under the command of General Sandiman Carey. He collected every man available in the vicinity, among them being three companies of American engineers, who thus had the first opportunity of proving the quality of the troops that were destined to play so decisive a part in the eventual defeat of the German onslaught. Indeed, the engineer 'made good' in the great emergency; and in that branch of the service not the least was the mining engineer, and the Tunnelling Companies whom he commanded. In a special order Sir Douglas Haig conveyed his "very keen appreciation of the fine work" which they had done during the four years. "In their own special work, mine warfare," he said, "they have demonstrated their complete superiority over the Germans." Whether in defensive mining or in offensive, "they have shown," he added, "the highest qualities both as military engineers and as fighting troops." We can take pride in this tribute to our fellow-miners and fellow-professionals on the other side; if our own engineer units did not have the chance to engage in similar underground warfare it was only because the American Expeditionary Force arrived at a time when a war of movement, started by the last German offensive and ended by their final retreat, had superseded the long period of stationary fronts. So the British had more experience in mine warfare than we did. A recent meeting of the Institution of Mining & Metallurgy in London was devoted to the work of the miner on the Western Front, an excellent paper on the subject being presented by Major H. Standish Ball. He stated that by the end of June 1916 a force of 25,000 men was employed wholly in mining operations, the officers being engineers with an experience of mining in all parts of the world. It was discovered during the War that the ordinary soldier had a deep-rooted objection to going underground, say, below 12 or 15 feet, whereas the miner was used to it and was willing to engage in the subterranean warfare that became an important feature of the campaign, in Flanders particularly. Listening for enemy operations was aided by instruments invented for the purpose. Fortunately the Hun was given to shouting, as well as talking, thereby allowing our side 'to keep tabs' on him. The range of sound in various rock formations was determined and the audibility of the various noises made in the course of mining was compared. Mine-rescue equipment was used to enable men to work in gassed ground. Canaries were used to ascertain the presence of an excessive proportion of carbon monoxide gas, formed by the explosions in the chalk. When the canary dropped dead, it was time for the men to get out, or wear a mine-rescue mask. It was related how the Tunnellers, as they were called, fought the Germans at a depth of 600 metres in one of the coal mines near Lens and how a guard of them was killed to the last man by the Germans, who took advantage of the down-cast air-current of a shaft to admit concentrated mustard gas into the underground workings. In the end the Enemy was circumvented in this locality by the construction of a concrete 'stopping'. In a paper read before the Canadian Mining Institute it is recorded by Capt. L. B. Reynolds that the Germans took the initiative in mining and they had all the best of it until the Tunnelling Companies were organized by the British and French in the summer of 1915. Miners were recruited hastily and rushed to the front, where they proved that "a man with the sporting instinct, engaged in a game into which he puts the hardest work of his life, is in every way the superior of the machine-made German soldier." We quote Capt. Reynolds. Just before the battle of the Somme the shafts in the chalk had reached a depth of 146 feet, and the Germans were working in an incline several hundred feet long that had attained a depth of 212 feet. The explosive generally used was ammonal, a combination of aluminum dust and ammonium nitrate. The aluminum dust was made, among others, by Mr. Charles Butters, at Oakland, as his neighbors learned to their discomfort, for this chemical readily undergoes combustion, causing minor explosions disagreeable to suburban dwellers. Here we may mention that the famous explosion, or 'blow', at Messines on June 6, 1916, heard by Mr. Lloyd George at his house near Reigate, in England, was carried out under the direction of Major Ralph Stokes, now a Lieutenant-Colonel on the Murmansk front in northern Russia. Colonel Stokes was then 'Controller of Mines', a post for which his experience in peaceful mining had fitted him admirably. He used to be our regular correspondent at Johannesburg ten years ago and volunteered for military service from New York, enlisting as a private in the Royal Engineers, during the first month of the War. We note also with keen interest that Major-General E. D. Swinton, who developed the tank into a potent instrument of war and contributed thereby so largely to the victorious result, acknowledged at a dinner of the Institution in London that he obtained the idea of an armored tractor from a mining engineer, Mr. H. F. Marriott, who was president of the Institution last year. General Swinton stated that in July 1914 Mr. Marriott wrote to him from Antwerp about an American caterpillar tractor that could go over rough country and climb "like hell." The machine was the Holt tractor, made at Stockton, California, and from the suggestion offered by Mr. Marriott the General, then much lower in rank, set to work to devise a bullet-proof machine that could overcome the German machine-guns; and how well he did it, we all know. One of the most spectacular, and most effective, bits of mining warfare was done on the mountainous Italian front by Capt. Gelasio Caetani, an Italian of noble birth and an American metallurgist of recognized distinction. On April 17, 1916, on the Col di Lana, at an altitude of 8110 feet, a drift 300 feet long had been extended under the Austrians, who were counter-mining; five tons of gelatine and nitro-glycerine were exploded, 15,000 tons of rock was lifted, 80 of the enemy were destroyed, and 179 survivors, including 9 officers, were captured. However, despite such brilliant exploits on several fronts, the mining phase of warfare proved less important than had been expected at one time. It must be remembered that at the beginning of the War it was thought that forts fifteen or twenty miles apart would suffice for the defensive; when the German onslaught exposed the weakness of this plan, the idea of 'digging in', of a continuous trench system parallel with the front, came into play. It was to break through the trenches that mining operations were started, but this proved ineffective, because the Germans countered it by a series of small forts, in the form of machine-gun turrets, at intervals less than their range, so as to constitute a continuous line of defence. Then came the tanks, which were the chief invention of the British and helped to end the War, as poison-gas had been a deadly trick adopted by the Germans in the early days of the Flanders campaign. Underground warfare, by means of mines, was romantic and spectacular, but it played little part in the final result; it was a failure except in a few uncommon instances as at Vimy and Messines, and on the Italian front; its real value was in undermining the morale, rather than the defensive works, of the Enemy, because the uncertainty of not knowing what was going on underfoot was intimidating and unnerving to his infantry. The aeroplane checked successful mining because it made it difficult to camouflage the waste-rock taken out of the underground excavations; moreover, the closeness of the water-level to the surface in some localities and the hardness of the rock in others made mining impracticable. Such work took time, any change in the Enemy's front frustrated it, and, as we have said, to the engineers of the American armies the use of mining, if otherwise desirable, was denied by the fact that the Germans were on the move, forward and then backward, by the time the American Expeditionary Force got into action. The mining engineer, however, wrote a thrilling chapter in the Great Fight for Civilization, and it should be recorded in the archives of the profession.

DISCUSSION

A Union of Technical Men

The Editor:

Sir—A union of technical men has been formed in British Columbia with the following objects: "(1) To obtain adequate recognition of technical work; (2) to establish scales of standard fees for consultations, and obtain recognition for the same; (3) to obtain equitable remuneration for salaried technical men and their assistants; (4) to secure consultation and employment for local members of the technical profession for work in British Columbia and to discourage the employment of outside men for technical work when duly qualified men are available within the Province; (5) to protect members when handicapped by extraneous influences in the execution of their profession; (6) to co-operate with existing professional societies in the furtherance of the above objects, and, while not interfering with their usual activities, to assist them in every legitimate manner that will tend to maintain or improve the efficiency, status, and remuneration of the technical profession; (7) to protect the public by encouraging the employment of qualified technical men." The secretary is Charles T. Hamilton, 570 Hastings St. West, Vancouver, British Columbia.

The idea of a union of technical men seems altogether at variance with one's ideas of what is right and proper, and yet, when one considers conditions as they exist today, the wonder is, not at the formation of a technical men's union now, but rather that such a union should not have been formed long ago.

The man who decides on a technical profession, after leaving school, has to spend four or five years at a college or a university to fit himself for his life's work, and then he is drafted into some industrial work and for the next five or six years, and not infrequently longer, he is employed at a salary which is less than that received by many a common laborer today. After a time, these technical men become superintendents of departments, and, ultimately, if they are fortunate, intelligent, and industrious, general managers of big industrial concerns, and it is in the hope of filling such positions, together with the pure love of their work, that has enabled them to carry on, often through long hours, at the mere pittance they receive. Have the employers in the past been dealing quite a fair hand to these men, or have they stacked the cards to their own advantage? The employer has demanded loyalty from his technical assistants, and usually he has received it, but has he, in his turn, been loyal to his technical assistants? Has he given a fair return for what he has received? I think he has not, and I think the formation of the technical union demonstrates that he has not. The average man, especially the educated man, dislikes to have to beg for an increase in salary. Ranged on the side of his employer against organized labor, he has seen what labor has been able to accomplish for itself by organization and combination. The high cost of living in recent years has made it almost impossible for him to live on the pittance doled out to him. Is it any wonder, then, that he, too, has decided to organize?

The Leaching of Flotation Concentrate

The Editor:

Sir—I read Mr. Middleton's article, on the leaching of copper concentrate, in your issue of June 7, with a great deal of interest. His ideas of the chemical treatment of flotation concentrates have much to commend them. However, the possibilities of leaching flotation or other concentrates, in the United States, has not been overlooked. Indeed, more attention is being given to it at the present time than ever before. The problem of the chemical treatment of flotation or of table concentrate is not an easy one. Much, if not most, depends upon the recovery of the copper from the leach solutions. Chemical precipitation, as so far developed, is out of the question, especially in the treatment of a concentrate. Even in the treatment of low-grade ores, chemical precipitation does not offer alluring possibilities. The chemical precipitate, which will usually be cement copper or copper sulphide, simply represents a higher-grade material, which, in turn, has to be smelted and refined much the same as an original ore. With iron precipitation, both the acid and the iron are irrecoverably lost. Even if sulphurous acid is used as the solvent, chemical precipitation appears to be inferior to electrolysis.

Manifestly, the hope lies in the electrolytic precipitation of the copper with the simultaneous regeneration of the solvent. It is doubtful whether any of the electrolytic methods so far made public will adequately solve the problem. They are not generally applicable. It is a question, even, whether much progress has been made in overcoming the real difficulty, and that is the neutralizing of the deleterious effects of the ferric salts in the electrolyte. Until that point has been adequately taken care of, the general application of leaching to copper ores and concentrates is not probable. When it has been adequately taken care of, it is reasonably certain that leaching will, to a very large extent, supplant smelting. The general application of leaching, to copper ores, must be attacked, not so much from the point of view of the extraction of the copper from the ore as from the viewpoint of the electrolytic deposition of the copper and the regeneration of the solvent. This is true whether the solvent be a chloride, a sulphate, sulphuric acid, or sulphurous acid. The greatest possibilities with either sulphuric or sulphurous acid are along the lines of electrolytic deposition of the copper and the application of the electric current to the regeneration of the solvent.

The phenomenally successful commercial results obtained at Ajo and at Chuquicamata do not affect the real issue, and, as a matter of fact, the vital point has not, even in those plants, been adequately met. At Chuquicamata the ore contains only a very small amount of iron, and it contains enough soluble copper to make the process practically self-sustaining in acid with electrolytic regeneration. Even at that it is necessary or desirable to discard large quantities of solution to keep down the ferric iron in the electrolyte. At Chuquicamata this discarding of large quantities of solution makes little difference, because the ore practically furnishes its own solvent for the copper. It would be unwise to attempt to duplicate the results obtained at Chuquicamata, as some have found out who have tried it, because the conditions there are exceptional and do not represent the ordinary leaching problem, either with a low-grade ore or a concentrate. At Ajo, a large proportion of the copper—approximately 25%—is precipitated with iron to reduce the effect of the ferric salts in the electrolyte. This copper precipitate is smelted much the same as a high-grade ore, or concentrate, with the regular furnace-charges. Iron precipitation of 25% of the copper also means a corresponding loss of acid. It is intended to maintain the ferric iron in the issuing electrolyte at about 0.5%, and only one-sixth of the copper is deposited in each cycle of the electrolyte through the cells. Even as small an amount as 0.5% ferric iron in the electrolyte is capable of doing a great deal of harm, and at Ajo it apparently does not take long to accumulate 0.5% ferric iron in the electrolyte, when 1.75 lb. of ferric iron is formed per pound of copper precipitated.*

Ferrous iron in the electrolyte is not particularly harmful; it may be decidedly beneficial. It is possible to get as large, or larger, efficiency with an electrolyte high in iron as from pure solutions, provided the iron is maintained in the ferrous condition. Ferric iron is harmful in proportion to its presence in the electrolyte. Many have tried, in a small way, to duplicate the success attained at Ajo and at Chuquicamata, without taking into account the elaborate precautions taken at those plants to overcome the deleterious effects of the ferric salts.

The real difficulty of copper leaching with electrolytic deposition and regeneration will not be overcome until the harmful effects of the iron in the electrolyte are adequately disposed of. It is fair to predict that when this difficulty is overcome, it will not be along the lines of purifying the solvent or of eliminating large quantities of solution to get rid of the ferric iron, but, rather, in making the iron work with the process and not against it. It would be much the same as in the ordinary concentration of ores. Before flotation was a success, high tailing-losses resulted from the tendency of certain minerals, such as chalcocite and chalcopyrite, to float away with the gangue. Numerous schemes were tried to make such minerals sink. The true solution of the difficulty came in helping the minerals to float, and not in trying to make them sink. And so it will be found in the electrolytic deposition of copper from impure solutions. The problem is not an easy one, but still, I am inclined to think, is quite capable of being solved.

In the treatment of concentrate the iron is an important factor. My own experience would indicate that it is quite impossible to make a large percentage of the copper soluble in water, without at the same time making also a considerable amount of the iron soluble either in water or in dilute acid. The difficulties, which are sidestepped at Ajo and Chuquicamata, where there is only a small amount of iron, are greatly magnified in the treatment of concentrates, which usually contain a high percentage of iron. If an attempt is made to roast so as to make the iron insoluble, the copper is also made insoluble, at least to such an extent as to make the extraction impracticable. The difference in the decomposition temperatures between the soluble salts of iron and the soluble salts of copper is too small to admit of close regulation in practical work on a large scale.

In conclusion, I might recall the statement made in the closing paragraph of my book on the 'Hydrometallurgy of Copper', published in 1912, before there was a single electrolytic copper extraction plant in successful operation:

"Copper is one of the most readily soluble of all the metals, and one of the most readily precipitated either chemically or electrolytically. Theoretically, the solvent processes, especially the electrolytic processes, offer all that could be desired, on ores chemically adapted; close extraction, cheap deposition, copper in its metallic form, saving of the precious metals, the installation of plants at the mines which may be operated in any unit and without admixture of other ores or fluxes. With these theoretical advantages it is reasonable to suppose that the chemical methods will ultimately be in as general use for the extraction of copper as the cyanide and chlorination processes now are for the extraction of gold and silver."

I see no reason now why this prediction will not be fulfilled. I am convinced now, as I was then, that the general application of leaching methods, especially to copper concentrates and high-grade ores, will depend largely, if not entirely, on the successful elimination of the harmful effects of the ferric salts in the electrolyte. I am convinced now, as I was then, that the solving of the problem of the ferric salts will be along the lines of making the iron work with the process, and not in eliminating it to such a degree as to restrict its capacity for doing harm.

Denver, June 9.

Blue Sky Laws

The Editor:

Sir—The question, 'Do Blue Sky laws protect the people against fraud?' is much discussed. This law in Nebraska has not been a protective measure, but, on the contrary, it has afforded an inducement to commit fraud; many industrial corporations were floated which proved worthless. While proclaiming to protect the investor from fraud, operating under the permit plan, it is nothing more than license to take money from the investor without a guarantee of honesty or soundness.

The law as administered is a joke, a snare, and a delusion; it protects none but stock and bond brokers, trust companies, and other Wall Street interests who are seeking to control all the industry of the United States, which cannot be done by any other method or scheme. The mining industry of this nation is hit the hardest by these laws and they violate the constitutional rights of every citizen in the country by refusing him the privilege to dispose of his personal or real property as he may desire.

The Nebraska legislature, after investigation, found that the Blue Sky law offered opportunity for the strong financial organizations representing Wall Street to monopolize the sales of securities within the State, thereby retarding the development of the natural resources of the State; that it afforded no protection to the citizens against the sale of fraudulent securities, but on the contrary was highly injurious to the business interests of the State, and a menace to legitimate development and industry; and that it deprived persons of liberty and property rights, all tending to injure and ruin the credit and operation of legitimate business concerns; and that it permitted the sale of stocks and securities that do not offer a fair return on the investment, while permits were granted to corporations to sell 6 and 7% preferred stock with no assets other than the money received from the sale of such stock.

The old law was repealed and a new one substituted granting the Governor and Attorney General authority to administer the same, leaving these officials to use whatever means they may decide upon to investigate the proposed industry at its expense, which in the opinion of many of the people is more autocratic than the original Blue Sky law and unconstitutional.

Every State in the Union has a law against fraud, and if these laws were enforced no person would be permitted to deal in fraudulent securities; but the Wall Street interests, realizing the enormous losses incurred by the sale of fraudulent securities, are seeking to blindfold the public by making it appear the Blue Sky laws protect them from fraud. I have read the Blue Sky laws of the various States, and have yet to find one that protects the investor against fraud, but on the contrary it permits a monopoly of the sales of all securities as well as exempting the stock and bond brokers, trust companies, and other Wall Street interests, allowing these hogs of finance to feed on the people. Blue Sky laws have done more to retard the development of the mining industry than any other act of our Government.

Mining is more or less a speculative proposition which involves some risk, but no person should be denied his lawful right to buy mining stock if he sees fit, but the mandate of the Blue Sky law says it cannot be done without its consent. Thus this industry is made to suffer for the reason that these officials are not competent to judge its value, nor will they do so from an unbiased standpoint.

These pirates of stock promotion are now clamoring for a national Blue Sky law, which should be fought tooth and toenail by every man interested in the mining industry for the reason that Blue Sky laws are autocratic laws, and are aimed directly at the man or corporation who seeks to develop our national resources. It is the worst form of tyranny, and it embodies and represents "taxation without representation." What we need today is not laws to restrict and destroy the mining industry, but laws that will encourage the development of our national resources, increase the opportunities for labor, and furnish this nation with gold and silver with which to pay off our National Debt, thereby increasing our prosperity.

Roy M. Harrop.

Omaha, June 1.

[In our issue of May 31 we published a letter on 'Justice to Our Native Young Men', signed "M. Stockholm." This was a typographical error, for the lady is named 'Stockham' and she is the wife of Mr. J. W. Stockham, of Warren, Arizona.—Editor.]

Zinc reduction works in Belgium consist of 14 smelters with a total of 50,696 retorts, 10 rolling-mills, with a combined capacity of 52,000 tons, and 10 chemical plants for roasting ores. About 60% of the smelting capacity can be said to be of modern construction. A plant at Rothem, with 3360 retorts, was completed just before the War, and one at Corphalie, with 2200 retorts, was built during the War. The tendency in the newer plants has been to increase to a considerable extent the mechanical handling of ores, also the mechanical charging and discharging of the furnaces. Belgian engineers have never looked with favor on the use of the large furnaces so common in the United States. The furnace generally used is one that has not over 200 retorts to the side, and it is only in the recently built plants that one finds the separate producers used, and in only a limited number have mechanical producers been used. The working floors of the furnace-rooms are well ventilated, and the hoods over the furnaces are connected with stacks for carrying away the zinc fume from the furnaces. For 10 years prior to 1914, 21.6% of the world's supply of spelter was produced in Belgium, but most of the ore was from foreign sources.—M. F. Chase in May report of the U. S. Bureau of Mines.

American Engineers in the War

On the eve of the departure of General O'Ryan with his troops from Brest, Sir Douglas Haig wrote him as follows:

"You are returning in victory from the first campaign in which American troops have fought on European soil, secure in the strength and limitless resources of your own great country on the other side of the Atlantic. The call of outraged humanity, which from the outset of the War sounded so loudly and closely in British ears, was heard from afar by the manhood of our sister nation.

"A people less far-sighted, less imbued with the lofty ideals of liberty, might never have heeded that call. You heard it; you gave heed; and when the time was ripe and every city, township, village, hamlet, and farm in your mighty land knew the full meaning of the desperate conflict raging beyond the seas, you flung yourselves into the fray, ardent and impetuous on the side of the right.

"You who now return to the homes that sent you forth in faith and hope to make, if need be, the supreme sacrifice for the belief that is in you, can say to those who greet you that in that triumph you have had your share. You can point to a proud record of achievement, to the months of patient, earnest training; to the incessant strain and watchfulness of the trenches; to the fury of great battles.

"You can point also to your sacrifices made with courage and devotion unsurpassed in all the dread story of the War, abundant in heroism, sacrifices which were the price of world liberty and peace, which you have helped so powerfully to build up anew.

"Returning, you and all ranks of the American Expeditionary Force carry back with you the pride, effection, and esteem of all who fought beside you, and not least of those with whom you share a common language and a common outlook upon life. The memory of our great attack upon the Hindenburg line on the 29th of September, 1918, in which the 27th American Division, along with the troops from all parts of the British Empire, took so gallant and glorious part, will never die, and the service then rendered by American troops will be recalled with gratitude and admiration throughout the British Empire.

"I rejoice to think that in the greater knowledge and understanding born of perils and hardships shared together we have learned at last to look beyond old jealousies and petty quarrels to the essential qualities which unite the great English-speaking nations.

"In bidding godspeed to you, whom for a time I was privileged to have under my command, I feel confident that the new era opened out before us by the appearance of American troops on the battlefields of the Old World will see the sympathy and friendship now established between our two nations constantly deepened and strengthened, to the lasting advantage of both peoples."

In Sir Douglas Haig's Official Dispatch he writes as follows:

"Other hostile attacks on both banks of the Somme were repulsed with heavy loss to the enemy by the 1st Cavalry Division, and the 3rd Australian Division, a battalion of United States Engineers rendering gallant service south of the river."

He concludes his dispatch by stating:

"Finally, I am glad to acknowledge the ready manner in which American Engineer Units have been placed at my disposal from time to time, and the great value of the assistaance they have rendered. In the battles referred to in this dispatch, American and British troops have fought shoulder to shoulder in the same trenches, and have shared together in the satisfaction of beating off German attacks. All ranks of the British Army look forward to the day when the rapidly growing strength of the American Army will allow American and British soldiers to co-operate in offensive action." [We refer to the subject on an editorial page.—Editor.]

Use of Manganese Di-Oxide Ore

By W. C. PHALEN

The quantity of manganese ore used in industries other than metallurgical vary from 25,000 to 50,000 tons per annum. The latter figure is probably more nearly correct. Most of the ore so used is the highest grade of pyrolusite (MnO_2) obtainable, and commands a much higher price than metallurgical ore. The manganese di-oxide ore is generally spoken of as chemical manganese ore.

The principal use of manganese ore, aside from its applications in the steel industry in the form of ferromanganese and spiegeleisen, is as an oxidizing agent. It is so used principally in the manufacture of dry cells, as a decolorizer in certain kinds of glass, and as a drier in oils, paints, and varnishes. The ore is also used directly or indirectly in the manufacture of various manganese chemicals. Many of the textbooks describe its reaction with hydrochloric acid as a source of chlorine. It is no longer used commercially in making chlorine gas, as the latter is an abundant by-product in the manufacture of caustic soda and potash. Some chlorine may be made by this method when the object is the production, not of chlorine, but of manganese chloride. It has been mentioned as a soil stimulant, but its value in the fertilizer industry has not been established, and so far as known it is not a constituent of any commercial fertilizer.

The gasoline engine gave the development and production of the present type of dry cell great stimulus. Its use in ignition systems demanded a cheap portable cell able to recuperate after comparatively heavy current drains. In 1897, its manufacture attained considerable volume. The present normal yearly requirements of this production include 25,000 tons of high-grade manganese di-oxide ore, an equal amount of carbon (petroleum coke and graphite) and 8000 to 10,000 tons of sheet-zinc, together with corresponding quantities of zinc chloride, ammonium chloride, paper, carbon electrodes, pitch, and sundry other substances.—Abstract from Minerals Investigation Series, No. 16, of U. S. Bureau of Mines.

Continuous Overflow and Its Effect on the Slag Loss of Reverberatory Furnaces

By OLIVER E. JAGER

Any noticeable reduction in the copper content of a reverberatory slag is an achievement worthy of comment, and calls for some inquiry into the causes effecting it. The present article refers to the practice at the Anaconda reduction works, and I am indebted to Frederick Laist, the manager, for bringing the subject to my notice. It will be shown that there was a large decrease in the reverberatory slag-loss after the introduction of coal-dust firing and the continuous flow. That this improvement has not altogether been maintained is due to the altered nature of the furnace-charge. The saving at present effected, however, is sufficient to merit consideration of the various changes that have taken place in the reverberatory practice. One of the most important of these is the elimination of skimming by the adoption of the continuous overflow of slag. To my knowledge, the adaptation of continuous flow to the reverberatory furnace had been suggested as far back as 1901, but it was not until the introduction of the very large furnace, fired with pulverized fuel, that the feature was introduced. The details of the continuous overflow of slag are as follows:

The reverberatory furnaces at Anaconda are 133 ft. 7 in. long by 22 ft. wide, fired with pulverized coal, and using side-charging. Each furnace smelts on an average 550 tons of charge per 24 hours, which will mean a slag production of about 369 tons, equivalent to a flow of about 15.5 tons per hour. It is this large quantity, of course, that makes a continuous flow possible, though it would be interesting to know on just how small a furnace it could be used, taking into consideration at the same time the heat in the slag and its silicate degree. The front of the furnace is protected by a large water-cooled cast-iron plate, 10 ft. 6 in. long by 2 ft. 3 in. wide by 4½ in. thick, set flush with the outside face of the brickwork. It passes beneath the skimming-door, the skim-plate being set above it. One or two openings suitable for tapping matte are left in it, and cleats are provided to hold the taphole-plates in position, matte being tapped from the end of the furnace. The door formerly used for skimming is bricked up, except for a suitable slot through which the slag escapes. The slag flows out of the furnace, over the skim-plate in the usual way, and into a curved launder of cast-iron, an inch thick, made in three sections bolted together. The launder is of semi-circular section, 24 in. wide at the top, with a flange 2 in. wide along the edges to retain the brick lining. This launder curves in an easy bend, changing the direction of the slag stream about 135°, and discharging it over the granulating jet. The slag travels about 12 ft. in going from the furnace front to the granulator. For a couple of feet outside the skimming door, the launder is kept covered by a few large lumps of coal and one or two brick slabs, with fettling thrown on top. Over the remainder of the launder a crust of slag soon forms, the molten slag flowing under this crust. This arrangement requires little attention, sometimes running for a couple of days without being touched, unless the matte rises in the furnace to a point where it starts to come over. The shooting calls the attention of the furnace-man, who shuts off the flow at the skimming door till the matte is tapped, when the slag stream is started again. When slag is removed from a furnace by skimming, there is always an admission of cold air to the uptake. This is avoided by using continuous flow. The furnace work is easier on the men, and there are fewer cleanings, etc., to be re-smelted. Continuous flow uses more water than the intermittent skimming method.

Coming now to the question of the copper content in the reverberatory slag, the first point that suggests itself is the amount of copper saved. Cutting down the slag-assay a few one-hundredths of one per cent does not appear an important achievement at first glance, and makes no appeal to the imagination of some furnace superintendents. But when this modest difference is applied to the tons of slag produced, and the calculation is carried on to show money saved, it demonstrates the value of making an effort to produce cleaner slags.

For the six-monthly period ending June 30, 1914, which was just prior to the installation of pulverized coal-firing and continuous flow, the slag contained 0.41% copper. Taking the last six months of 1915, during which all furnaces were operating under the new system, the figure is 0.32% copper. While this decrease of nearly 0.1% was possible under the conditions prevailing at that time, it has not been attained with the present character of reverberatory charge, so that 0.35% copper is now a good average figure. The change in the charge is due to the large quantity of flotation concentrate now treated. This extremely fine material does not smelt as easily as the coarser quality formerly treated, and has a marked tendency, while being charged, to produce dust that gets into the slag. Owing to the fact that the blast-furnaces are not in operation at present, there is some high-grade partly oxidized material going to the reverberatories, and unmixed with the remainder of the charge.* This also has an adverse effect on the slag-assay, though the actual effect cannot be very great, as the tonnage of this material amounts to less than 8% of the total charge. Under normal conditions at Anaconda, seven furnaces are operated in the reverberatory building, smelting a total of 3850 tons of charge per 24 hours. Of this tonnage, 67% goes into the slag, giving 2580 tons of slag. Therefore, a decrease of 0.06% copper in the slag-assay means an annual saving of 565 tons of copper. Assuming the recovery of 98% of this copper, and that it sells for 16 cents per pound, there would be an annual saving of $177,000. Comparing the slag-analyses for the two above-mentioned periods with that of the present slag, no difference is to be found in their silicate degree. A calculation of oxygen ratios shows the slags to be extremely uniform, corresponding closely to sesqui-silicates, so that no question arises as to any difference in their fusibility.

---

*Oliver E. Jager, 'Exit the Blast Furnace', M. & S. P., June 21, 1919.

It appears to be well established that the lower copper-assay is due to the continuous flow, though it might be argued by a meticulous person that it is really due to the introduction of coal-dust firing, as it was the latter process that brought about the adoption of continuous flow. When this method of firing was first installed, the furnace was skimmed in the usual way. It was soon found, however, that the ash from the coal formed a blanket of slag on top of the molten charge, and that this slag blanket was evidently holding up dust from the charge, thus increasing the copper loss in the slag, as samples of the slag blanket showed an abnormally high copper content. With a continuous flow, the slag-blanket is held back in the furnace, where the resulting condition of tranquillity allows a better separation of entrained metal. This is also assisted by the introduction of fine lime-rock through doors provided on either side of the skimming-door, as any tendency of the slag to thicken is overcome by the action of the flux.

In addition to the effects of the continuous flow, a significant factor in the reduced slag loss is the introduction of a proper system of mixing the charges going to the roasters.† Considerable care is now taken to produce a self-fluxing calcine, since it has been proved that sudden variations in the composition of the charge will produce similar variations in the slag-assay. For instance, a sudden excess of silicious material will upset the furnace operation by interfering with the proper fluxing of the charge, leaving a certain unfluxed portion to be taken care of by a subsequent charge. In other words, a 'floater' is formed. This condition was more often encountered in the old practice of dropping large charges into the centre of the furnace, than with the present system of side-charging, where the feed is introduced more gradually.

Another factor, due to the practice of side charging, is that there is no longer a large bath of matte in the furnace. With this lack of storage space for matte inside the furnace, there is more liability of the matte rising and getting out with the slag

Summing up, the continuous flow is the most important factor in the reduction of the slag-loss (particularly when using pulverized coal as fuel), as there is a better opportunity for any entrained metal to settle out of the slag blanket, the quiet, steady flow being more conducive to this than the sudden rush of the large slag stream produced when skimming. There is no doubt that, under present conditions of operation, were skimming in vogue the slags would carry more copper than they do with continuous flow. The proper preparation of the charge also plays a considerable part in the production of slags of lower copper content, provided its effect be not nullified by the addition of large quantities of flue-dust, or other material not figured when making up the roaster charges. Firing with pulverized coal gives a slightly better combustion of fuel and more regular furnace conditions than grate-firing, as the former system produces the conditions necessary for proper combustion and heat radiation inside the furnace, though it has not been shown that any higher temperature is obtained. Side-charging favors the production of cleaner slags, though the diminished matte-space has a tendency to offset this. In conclusion, it may be said that, considering the general composition of the present reverberatory slag, it is as clean as a blast-furnace slag would be, if the latter were produced under prevailing conditions at Anaconda.

* * *

THE IRON INDUSTRY in Shansi province, China, is the oldest in the world. The ore is, unfortunately, in irregular lenses, the average thickness being about 1 ft. Mining this ore by modern large-scale methods is therefore impossible, although much of it can and is mined by native methods. The estimated quantity in Shansi is 300,000,000 tons, although this quantity is necessarily approximate. In other parts of China there is approximately 300,000,000 tons more, of which at least half can be worked by modern methods. In 1915 the total production of pig-iron was about 300,000 tons. Of this amount, 136,541 tons came from the Hanyang Iron Works and 29,529 tons from the Sino-Japanese Coal Co. at Penshihu. The rest came from small native furnaces in various parts of China. Besides supplying the Hanyang works, the Tayeh mine exported 298,350 tons of ore to Japan. The estimated total production of pig-iron in 1918 is 500,000 tons. The iron-ore deposits are now controlled by either Chinese or Japanese interests, the Chinese government making efforts to obtain control of deposits not already mortgaged to the Japanese.

* * *

MANGANESE MINING costs $9.50 per ton in the Erickson district of Utah, $8.25 in the Cartersville district of Georgia, $5 to $8 in Cuba, and $5 in Brazil. The Utah ore is from deep workings, the others from surface operations. The estimated average cost per long ton of manganese ore delivered to the consumer during 1918 was $29.70 per ton for domestic, 41% oxide and 36.5% carbonate, and $30 and $23.50 for Brazilian and Cuban 45 and 38% ores, respectively. The future cost will be about $24.65, $14.75, $18.50, and $16.50, respectively.—C. M. Weld and W. R. Crane of U. S. Bureau of Mines.

Industrial Co-operation

By W. R. INGALLS

*A few weeks ago in delivering an address before the Mining and Metallurgical Society of America, I took as my theme the 'Economic Duties of the Engineer'. In the address to which I have referred I expressed the fundamental idea that the civilized world has experienced such great losses of capital and man-power through the War that it is confronted by grave prospects unless the losses be off-set by great increase in efficiency in production, which will likely require an industrial reorganization. We, and especially we engineers, must strive for that and we may achieve it, but as an ominous counter-agent I see the spread of Bolshevism and many economic fallacies. I urged it therefore as one of the essential duties of the engineer that he saturate himself with sound economic doctrine and prepare himself to spread the gospel. I pointed out, that labor as the residual claimant upon the produce of industry already gets about 80% of the whole, leaving to capital only what comes to about 4% on the total investment, and that if labor should attempt to seize that moderate share and should succeed in doing so, it would meet with the disappointment of the child who grasps a soap-bubble; that the grievances of labor refer in the main to inequalities in distribution among its own classes; and finally that the only way of maintaining or improving the welfare of labor is to enable it to produce more. In order to enable it to do so, we must contemplate industrial reorganization and must accustom ourselves to think in terms of industries as a whole.

What I am going to say will be, perhaps, different from what you expect. I am not going to tell you that we must prepare for a new social order, or that the day of industrial democracy has come, or that henceforth the workers—meaning those who labor mainly with their hands—are going to run things. There has been a lot of talk of that sort, which has been sentimental, fallacious, and mischievous. On the contrary, I shall tell you that economic law is going to prevail and determine what people will do, and the less attempted interference with it there is, the better will everything be. I am going to tell you that labor instead of holding the gains that it made during the War is in danger of falling below the scale of living before the War. When I say labor, substitute people, for in the main the laborers are the people. We do not want to see any such downfall. It can be averted only by industrial co-operation. As I proceed you will see that what I mean by industrial co-operation is nothing like what some people mean by industrial democracy. There is great unrest among workers all over the world. This is mainly economic, and is based on ideas ranging from the moderate thought that labor does not get its fair share of the produce of industry to the extreme thought that it ought to recover what it thinks has been stolen from it in the past. Before entering upon constructive considerations, let us pause to examine if there be anything essentially wrong in the arrangements the industrial world has already worked out for itself, not merely in one country, but in all civilized countries, for the system is everywhere about the same.

In my previous paper I argued that there is nothing essentially wrong, for the reason that labor is the residual claimant upon the produce of industry, taking all that remains after the deductions of the shares of the landlord, the capitalist, the entrepreneur, and the State; that even if those deductions were not made labor would not get any more; that such inequalities in distribution that exist are not between capital and labor, but are among classes of labor itself. The expression that labor is the residual claimant upon the produce of industry is one of the things that I have been asked to explain. It is in no way a new thought, but rather is it classic economic doctrine, advanced by Jevons and developed by General Walker. I can offer no explanation so good as to quote freely from General Walker, without however using his exact words or confining myself simply to his statements.

On the lowest grades of land there is no rent. The cost of producing from them so much as must be produced to supply the needs of the people determines the price of agricultural produce. The rent of better lands is the excess of their produce after the cost of cultivating the no-rent lands has been paid. This rent does not affect the price of agricultural produce and does not come out of the remuneration of the agricultural laborer. The laborer cannot get it, or any part of it, by any economic means. It must go to the landlord unless it be confiscated by the State, or ravished away by violence, and in either of those events it will soon cease and no longer accrue for anybody.

The remuneration for the use of capital must be high enough to induce those who have produced wealth to save it, instead of consuming it. Manifestly what is paid as interest for the use of capital is no loss to labor, for it makes more produce out of which labor benefits. Indeed, the higher the rate of interest the more is the benefit of labor. The worst thing that could happen to labor would be such a curtailment of the rate of interest, either from economic or arbitrary causes, as would diminish the incentive of people to save and induce them rather to gratify personal appetites and tastes as consumers.

Profits economically partake of the nature of rents.

---

*An address prepared for presentation at the annual general meeting of the Canadian Mining Institute.

Just as there is a class of no-rent lands so is there a class of no-profit employers, the need for whose produce determines the market-price. From the point of no-profit production, profits range upward through the degrees of moderate profits, liberal profits, grand profits, monumental profits, but these consist wholly of wealth created by the entrepreneurs themselves and no economic means would carry any portion of them permanently to wages. To be sure, they may be taken by the State as taxes, and by the State paid out in extravagant wages, but this destroys the economic balance and produces conditions whereof the result is that nobody makes any profit, industry languishes and labor suffers. We are now witnessing just such a condition.

The matter of profits is one of the most complicated of economic questions, or, perhaps I should say, one that is a subject of much popular misconception. Capitalists themselves are responsible for much of this through the common desire to make a good showing, and disinclination ever to allow sufficient for the depreciation and obsolescence of plant. In the metallurgical industry we see repeatedly how plants have to be discarded and rebuilt entirely. How others have to be abandoned owing to failure of the mining districts that once supported them. How industries become over-built in order to supply temporary needs with the eventuality of surplus capacity that has to be thrown away. Thus the American zinc industry in 1915-'17 realized fabulous profits on paper, but a large part of them was re-invested in plant that subsequently ceased to have any earning capacity. Sometimes special conditions preclude a venture unless an extraordinary apparent profit can be expected. Thus, I once arranged for the purchase of a zinc smelter on the basis of an annual profit of 50%, for I could not estimate the endurance of natural-gas supply for but little more than two years. The purchasers merely got their money back plus an annual interest that really did not justify their risk. The exaggeration of profits contributes to the dissatisfaction of laborers who reason that their wages are pitifully small while the earnings of their employers are extravagant, and fail to appreciate that much of those earnings is merely replacement of principal or reward of extraordinary risks, without the prospect of which industrial progress would be checked. But after all, this is going into details and losing sight of the economic situation in its entirety, which is a common fault and source of misconception.

Rents, interest, profits, and taxes being deducted from the produce of industry all the rest goes to the laborers. "So far as, by their energy in work, their economy in the use of materials, or their care in dealing with the finished product, the value of that product is increased," says General Walker, "that increase goes to them by purely natural laws, provided only competition be full and free. Every invention in mechanics, every discovery in the chemical art, inures directly and immediately to their benefit, except so far as a limited monopoly may be created by law for the encouragement of invention and discovery."

General Walker illustrated this by supposing a community to be engaged in a certain production, which is divided among rent, interest, profits, and wages. Let it be supposed that over-night a higher class of population be substituted, and that it produces 5% more of goods. To whom does the gain go? Not to the landlord, for the material used makes no larger draft upon the land than formerly, and hence calls no lower grade of land into cultivation. Not to the capital class, for no more tools are required than formerly. Not to the employing class, for the substitution of intelligent workmen for those of a poorer quality has no tendency to drive production down to a less efficient grade of entrepreneurs. On the contrary the effect would be to raise the line of no-profit employers from which the profits of successful employers are measured upward. Hence the gain must go to labor, for it cannot go to anyone else, and this, says General Walker, is what is meant by the laboring class being the residual claimant upon the product of industry, which upon the assumption of perfect competition is both profoundly true and of illimitable importance in economics.

This is an expression of a great economic truth in the abstract, but it may be put in a definite statistical way. We know it to be the truth not only from scientific deduction, but also from examination of the income of nations and the distribution thereof. Numerous studies of the income of both Great Britain and the United States show that of the whole produce 60 to 80% goes to labor and that the remainder is but a relatively small return on the capital used.[†] But we are able to show and to say a good deal more than that, to wit, that during the last hundred years of great industrial development the major part of the benefit has accrued to labor.

It was the theory of Karl Marx, from whose teachings are derived so many of the fallacies of the present time, that labor, in its narrowest sense, produces everything, and therefore that labor should have all that it produces. That idea is frequently expressed now, all over the world. We have already seen that labor gets almost all as it is, and what remains it would not get, for if profits for example are the reward of intelligence—the removal of intelligence would remove profits also. So long as the world was dependent upon mere man-power there was no very great advance in the wealth of nations beyond what was due to increase in population. There is no good reason to believe that an Englishman in the reign of George IV could carry any more weight per hour or for any more hours, or could exhibit any other superiority of physical power, than an Englishman in the time of William the Conqueror. The great increase in production has happened during the last century and a quarter and has not been because men have grown any stronger; but because mind has taught labor how to become more effective and has provided it with machines and with organization. It is the minds of the captains that have produced the great increase in wealth and to those captains might reasonably have accrued all that they earned, but the economic principle that labor is the residual claimant prevented any such result, even if it were desired. The income of England in 1801 was about £180,000,000. The income of the United Kingdom at the same rate, but allowing for the increase in population, in 1907, would have been about £900,000,000. Actually it was about £1,950,000,000, excluding the revenue from foreign investments. In the words of Mallock, "the mind of the larger employers was the primary producer of an income of some £1,050,600,000 added to an income that would otherwise have been £900,000,000 only." Then he shows conclusively that of this increment the representatives of Mind got only about £250,000,000 for themselves, including both profits and the interest on industrial capital.

[†] In my January address I indicated labor's share of the produce of industry of the United States as having been approximately 80% in 1916. Since then I have seen Dr. Bowley's excellent paper on the division of income in Great Britain, in which he arrives at the conclusion that labor's share in that country in some years immediately preceding the War was slightly more than 60%. There is some reason to suppose that labor's residual share in the United States is larger than it is in Great Britain. However, I am giving these figures only as rough indications.

I have shown, I hope, that there cannot be anything essentially wrong in the existing system of the distribution of the produce of industry as between labor and capital. Labor cannot divide among itself any more than there is to divide, that is, the total of what is produced. That is self-evident. It may attempt to seize the modest share of capital, but if it succeeds in doing so, that share dries up. If it confiscates capital itself it does not gain anything, for capital, without the directing minds to use it productively ceases to be of advantage to anybody. The experiences in Mexico and Russia have shown what happens. The Bolshevists of other countries will lead to the same end if they have their way. Why is it that while socialists are shouting from soap-boxes, inflaming the populace with irritant poisons, while doctrinaires who hold professorial chairs are issuing fallacies, while a motley crowd in Russia is performing the most cruel and disastrous experiment ever known, we cannot drive into the heads of people that even as things are under the capitalistic system they get all they can, that they can get no more than they produce, and that it is not the power of the mass, but rather the minds of the few that have uplifted them to the stage of comfort that they enjoy today, which is vastly superior to what it was a century ago. If the Marxian doctrine had been true labor would be paid now what it was 100 years ago, no more.

It is of profound importance to make the millions of workers see things correctly, for they are blindly approaching a time when adverse economic conditions are going to drive them, and no socialistic ranting or paternalistic policies by the governments are going to help them. The world has become so much poorer by the squandering of wealth and man-power during the War that no advance in the scale of living is to be expected from it. The prospect is just the reverse. The farmer does not lose his cattle and install improvements in his house because of his loss. The people of a city do not become profligate buyers of automobiles after a conflagration has swept away their houses. No more do nations become prosperous because war has consumed their substance. Instead of labor holding what it has gained during the War it is probable that it will suffer a relapse to a condition inferior to what it held just before the War, although the unions will struggle bravely against it. Fortunately we shall not see a loss of economic improvements, such as safety measures in industry, the provision of proper working quarters and conditions, because they are economic; but labor is in danger of losing the eight-hour day for the simple reason that it will have to work nine to ten hours in order to produce enough on which to live.

The inevitable will be violently but impotently resisted by the workers, who will not understand the compelling forces, and therein is something very pitiful, for the workers could do so much to help themselves if they would. "When men take twice as long as they ought in building their own houses," said Sir Charles Allom recently, "they increase their rents and thereby increase their cost of living before they increase their wages." He estimated that the workmen in the United States waste time to the value of over $8,000,000,000 per annum, an estimate that is only rough and requires a good deal of explanation, but nevertheless conveys an idea of the magnitude of this economic loss. He adds correctly, however, that capital "is the mainspring of enterprise and advancement and labor's profit. Rich men are rich not because they have robbed the workingman, but in spite of the workingman having robbed himself." But, alas! we cannot make the workingmen see this and try to help themselves, and therefore we are obliged to try to make good the losses of the world, avert backsliding and lay the foundations for further progress without their aid and even in spite of them. And thus, after this long preface I come to my thesis of industrial co-operation as one of the means of economic improvement that in this juncture is essential.

Now, economic improvement may be defined as the avoidance of waste. I can think of no better definition. I do not mean merely the elimination of obvious wastes, such as were features of many gospels that were usefully preached during the War, but rather the major things that we do not yet regard as wastes, or if so, do not yet know how to eliminate them. The diversion of unnecessary men, the prevention of misdirected effort, the increase in the foot-pounds of the man-day of work are all forms of cutting out the waste. If the railways of the United States could by virtue of improvements in organization, invention of automatic devices, etc., be operated with only one million men instead of two million there would manifestly be an enormous saving of labor, which could be diverted to the production of something else. The avoidance of waste is therefore fundamentally the avoidance of the waste of labor.

I must now pause to refer to another economic obstacle. I have already described the discouraging impediment that exists in the fallacies of the workmen. We have also to contend with something quite similar and equally serious in the minds of a large part of the employing class. This is the idea among thousands of them that they too do not get their due, that something is somehow stolen from them, in short, that they can get more than they produce. This idea finds expression in agrarian movements among the farmers to contest what they deem to be robbery by the millers and railways. It finds expression in the never-ending grievance of miners against the smelters. During the War the attitude of these people assumed the form of a rapacity that was only a little less extortionate than that of some classes of labor and which has a very ugly and dangerous aspect now. During the War governments could take billions of dollars from some classes of people and scatter it among others without thinking of anything but the immediate object of winning the war. There developed the pestilential idea of price-fixing, which it is going to take a long time to eradicate. I do not intend to discuss that intricate subject, which would require much more time than is at my disposal now, but I am going to point out some of the mischievous things that are inspired. An example is this: In the United States we had very high prices for sheet-zinc, due to deficiency in rolling capacity. The Government fixed a restrictive maximum, which was still high and the market-price stuck to that maximum owing to the shortage in supply. Ore-producers in certain districts claimed a participation in the profits of the rollers, who were also smelters, and through the agency of the Government obtained a grant of an ore-price far above the market-price. The ore of this grade being more than the smelter-rollers could take, the demand was allocated among themselves by the miners, who sold their surplus at the market-price. Thus instead of letting the rollers make monumental profits and recovering them through taxation, the profits were divided among numerous ore-producers, who frettered them away.

But to finish this story. Although the production of zinc required no stimulation, there being on the contrary over-production, the miners deemed the time ripe to compel the smelters to pay them the prices they would like to have, and the Government bowed to them and arranged things. This killed the goose that laid the golden egg. The smelters assented to the scale and then did not buy any ore at all, drawing upon their stocks and diverting their buying to other districts that were eager to sell at the market-price.

There was a great effort made to have the Government guarantee minimum prices for some ores. The legislation was not enacted until about a month before the Armistice, and then not in the form desired by its promoters, but as a result of concerted action, there is now to be an indemnification of mining losses incurred, it is alleged, in anticipation of the legislation, although in fact the bottom had begun to drop out of the markets two months previously.

The cotton-growers were immune against any price-fixing, and had a very sporting and highly profitable time, but now that the price of cotton is declining in company with that of other commodities they are demanding a guaranteed minimum.

These instances illustrate one form of industrial co-operation, a form of co-operation in dipping into the treasury of the public, but it is not the kind that I mean, and it is a kind that will infallibly make everybody poorer, the co-operators included. On the contrary, one of the first essentials now is for every country to rid itself of its useless industries. If anybody is trying to raise bananas in Canada (I suppose it might be done under glass) he is not adding anything to the wealth of the country. He is subtracting from it. Instead of encouraging him, he ought to be suppressed as a national waster. However, I will give a less extravagant example of my meaning. We have in the United States a considerable quicksilver industry, but owing to the poverty of our ores the metal is costly to produce. We can buy quicksilver much more cheaply from Spain where there are rich ores. Our domestic industry can be kept alive only by a high protective tariff. That would be a very costly tax upon all the people, a national loss of money, in order to afford a precarious existence to a few people who would better be doing something else. I shall immediately hear the suggestion of the necessity of military preparedness. Very good. Quicksilver is a highly essential article and last year our munitions requirements took a large part of the domestic output, but a little figuring will show that it would be far cheaper for our Government to buy from abroad the supply for several years, and pay storage and interest charges than to keep our own mines going.

There are not a few industries of this class in the United States, and in Canada you have them, too. I am not depreciating the principle of a protective tariff, or even of a bounty, in all cases. A country may have national resources, or opportunities, for the development of which a temporary stimulus may be helpful. In such a way was the manufacture of tin-plate in the United States established as a great industry. But the maintenance of production out of the poor hopeless ore deposits by means of donations at the expense of all the people is an economic crime. I repeat therefore that one of the first things in the way of industrial co-operation that should be done is the elimination of useless industries. I think that it is a great function of professional organizations like this to study and determine what are useless industries. Governments, subject as they are to political influences, cannot in time of peace, whatever they may have done in time of war, form so impartial an opinion. Indeed, the suppression of non-essential industries by the war-boards was generally of useful industries for the sake of those that under peaceful conditions would be useless.

Probably there are rather few absolutely useless industries. If the number of them were large a country would soon become bankrupt. Most industries are useful and profitable to a more or less degree, and assuming that national resources afford the proper foundation their economic position is probably in proportion to the co-operation that exists in them. I shall continue my illustrations to the metal industries, feeling a certain confidence that what lessons may be deduced from them and what opportunities for improvement in them may be discerned, may be extended to almost all other industries.

It seems to me that of all our great metal industries copper is the best organized industrially and affords the best example of industrial co-operation, which is the more remarkable in that there is no formal association, nor indeed is there any need for one. The satisfactory situation in this industry has resulted from the transparency that has been produced in it. By transparency I mean the excellent knowledge about all its affairs that is possessed by everybody, resulting from the withdrawal of all veils so that everybody can see through everything. The production is in the hands of a relatively small number of companies, and even the smaller of them are relatively large concerns. The controlling interests are fewer than the producing companies, but not so few that there is not sharp competition among them in the market. There is a perfect exchange of technical information, both through the medium of the technical press, the transactions of the societies, and inter-works visits. If at one works some new improvement is developed, such as coal-dust firing, no effort is made to keep it a secret, but rather is there an *esprit de corps* which leads to the prompt spreading of the details and the adoption of the new method wherever advisable. There is a similar publicity as to the methods of accounting, operating costs, and financial positions. The industry has learned the value of prompt statistical information and now co-operates as a matter of course in furnishing the data for it. Producing a metal that is generally in demand and for which there is no substitute, with conditions that have forced producers to resort to poorer and poorer deposits and to devise improved means permitting their profitable exploitation, the copper industry has escaped the burden of over-capitalization. The industrial co-operation in the copper industry, developed naturally as it has, and both tempered and stimulated by commercial competition as it is and should be, is so excellent that I am unable to suggest anything that should be done to improve it, except even better statistical information.

Among American mining and metallurgical industries I am inclined to put iron and steel next to copper in industrial co-operation and therefore in general efficiency, but I am not so familiar with it and therefore hesitate either to commend or criticize. The metallurgy of iron and steel certainly does not figure in current technical literature to anything like the extent that does the metallurgy of copper and data of cost of production and other things are far less easy to ascertain. The industry is well provided with statistics of production and some other rudimentary data. It is chronically overbuilt and subject to the alternate conditions of feast and famine. I feel convinced that there is much less transparency in this industry than in copper and that the state of what is only translucency or perhaps I should say semi-obscurity, is an obstacle that might advantageously be overcome by the right kind of industrial co-operation, and I say this although there is an industrial organization for just that purpose.

Passing to the lead and zinc industries, we find less satisfactory conditions. Both the smelting of galena ore and of miscellaneous silver-lead ores, which result in producing the pig lead of commerce, have been brought to high degrees of perfection to be sure, but the industry as a whole exhibits very little co-operation. Thus, until within a few years the mining companies of the south-eastern Missouri district, one of the major sources of lead supply, had very little to do with each other, although the exchange of information respecting the ore deposits would have been of great value to all. In the marketing of pig lead all of the producers were hostile and secretive. There were no statistics available except the annual figures as to production. There was always mystery respecting unsold stocks. Amid this obscurity as to commercial conditions, the market was subject to sharp ups and downs, affording a lucrative hunting ground for speculators. In silver-lead smelting a large part of the works had passed into the hands of one great company, whose relations with its clients—the sundry ore-producers—were neither of the happiest nor conducive to the best interests of both parties. In British Columbia, where there is only one smelter, a similar condition of affairs has existed and still exists.

I do not intend to digress into any lengthy discussion of the chronic controversy between miners and smelters. The clearing-house among Colorado smelters, immediately preceding the general consolidation of American smelters about 20 years ago, was an excellent example of effective industrial co-operation. Previously no smelter could work to the best advantage; for needing ferruginous ore, calcareous ore, silicious ore, plumbiferous ore and argentiferous ore in certain definite proportions, he might be short of one or two classes and consequently unable to compound the most economical smelting charge. The clearing-house became a reservoir and equalizer which improved economic conditions to the advantage of everybody, miners as well as smelters. The consolidation perfected this idea and in the course of time improved greatly its technical practice. While the company out of this derived large profits for itself, as it should have done, without any doubt the ore-producers benefitted even more. A large part of them would not be able to operate at all today were it not for the economies of the big company, whose margin per ton of ore treated is, on the average, no more than reasonable, and indeed I might say, modest. In my own study of the affairs of this company about 10 years ago I showed that its profit on all ore smelted was only about \$2 per ton, while in some important districts it was only \$1. Nevertheless, it is undeniable that on the part of the miners, not only in this industry but also in others, zinc for example, there survived undisguised feeling of suspicion and hostility toward the smelters, instead of which there should be frankness, friendship, and co-operation. Who will gainsay that if such a relationship could be inspired it would fail to be of great advantage in improving the efficiency of the industry as a whole? In the commercial end, the marketing of the product, and in general matters of administration and introspection I am sure that the leaders of the lead-producing companies profited greatly from their association during the War. They learned something of what it means to think in terms of the industry, and not merely as individuals.

I can illustrate best what I mean by thinking in terms of an industry by referring to an address that I made to the zinc-producers of the United States last July. The American zinc industry at that time was already in a dangerous state owing to the aftermath of the feverish stimulation in 1915 and 1916. The fabulous prices for spelter during that period had the natural effect of increasing producing capacity enormously, primarily owing to more production being needed irrespective of cost; but from the outset it could be safely prophesied that the day would come when there would be a surplus of capacity and ecstasy would be followed by depression. I shall not spare the time to trace these interesting experiences in commercial economics. Suffice to say that the early part of 1918 saw the extinguishment of the ephemeral plants, while of the substantial concerns remaining, three-eighths of their capacity was idle at the mid-year, with fair prospects that it, representing a capital of $10,000,000, would be idle indefinitely. Besides this the industry was threatened with serious alterations in economic conditions. In this juncture I advised the industry to co-operate in a propaganda to increase the use of zinc, with the aim of substituting it for dearer metals, and to take steps to increase efficiency in production and selling, among which would be a well-developed statistical service, and the organization of a good system of uniform accounting. The desirability of increasing the uses of this metal, from the standpoint of the producers of it, is of course self-evident. But with respect to increasing the efficiency in selling and producing, the expression of the means in general terms will perhaps fail to convey clearly the ideas, wherefore some elaboration may be welcome.

The foundation of successful marketing is knowledge of conditions, both as to consumption and production. If everybody could see these conditions at all times the markets would be comparatively stable, just as are those for aluminum and nickel, which are controlled, on the producing side, by monopolies. Now, I do not intend to argue in support of the monopoly idea, my argument will be quite the reverse, but it is clear that the director of a monopoly, having full information respecting conditions of production and good information as to consumption, can eliminate minor fluctuations in price and needs conform only to broad swings of economic conditions. I do not think that monopoly, not even beneficent monopoly, is a good thing, but certainly it arrives at the result of relatively stable prices, and the nearer the same result can be attained under conditions of free competition the better it is for everybody except speculators. Manifestly the only means of accomplishing anything of that sort is knowledge, and fundamentally statistical knowledge. I think that it can be shown that in industries that have acquired such knowledge the fluctuation in their markets have moderated, but in no case is the statistical service yet as good as it ought to be.

I need scarcely point out the incalculable benefit both to capital and labor if it were possible to determine the state of economic conditions more promptly and more accurately than is possible at present, enabling both producers and consumers to cut their cloth accordingly, and incidentally eliminating the speculator, who in our present organization is simply a person who is more gifted for seeing in the dark than are most. There would be less waste of capital in over-building means of production, there would be fewer periods of over-stocked markets, and the lot of the workingman, assured of more regular employment, would be infinitely better. Of course, the last is just one of the things that socialists talk about effecting, and that is one of the expressions of a justifiable discontent, but the cure for it is not state control of industry, nor industrial democracy, but merely industrial co-operation in a sound and simple manner.

The improvement of efficiency in production is neither so simple nor so easy. I put this under the head of organization of a good system of uniform accounting, for until that is accomplished nobody can know just how the component parts of an industry stand, and what ought to be done to improve things generally. No man can know whether his business is being conducted efficiently or not unless he knows not only his own costs, but also has some standard with which to compare them. By such comparison he may ascertain that his costs are too high, and then upon analysis he may find that he is employing a wasteful type of furnace which it would be economical to discard, even at the expense of a new one of greater first cost. By this time the services of the engineer have been called in, which services are never invoked soon enough or often enough, or extensively enough. In some districts where the mines are small it would be advantageous for their owners to co-operate in retaining the services of one or more engineers for general advice. A general industrial association should have experts to aid the district and local groups. Manifestly, there would be no reason, whatever, why a company sufficiently strong and enlightened to do its own engineering and its own research work should not continue to do so. However, that should not cause the big company to hold aloof from the general co-operation.

The strong must help the weak, and in most cases it is the weak who know the least about their own business. Moreover, I conceive that it is in the interest of the strong to help the weak, and certainly it is never to their loss. The Anaconda Copper Mining Co., which has been a leader in developing the practice in copper metallurgy, has been generous in communicating information to other producers, and so far as I know has not lost anything by its generosity; rather has it gained something for itself. I have an idea that no one concern in any business can be very prosperous unless its industry as a whole is fairly prosperous. Let us suppose for example, that in Detroit, which has become a great centre for the manufacture of automobiles, there were one or two concerns, which by reason of excellence in design and construction of their cars, good business management, etc., stood head and shoulders above all the rest as commercial successes. The fact that Detroit had become such a centre inspired many kinds of accessory and elemental manufactures, even to the rolling of sheet-copper and the production of pig iron. Suppose now that a general blight overtook automobile manufacturing, compelling many makers to suspend and consequentially many of the industries that supplied them with necessary things; but that the one or two conspicuous concerns escaped the blight. Certainly they would not escape the consequences, if the local rolling mills and manufacturers of rough parts ceased production and if the population of skilled labor dispersed. The connection between one concern and all of the rest in its industry may not always be so clear as this, but that there is a connection is sure, and it is a reason why the strong should help the weak.

Now, labor has a direct interest in this branch of industrial co-operation, just as it has in the statistical service. Earlier in this paper I have pointed out how labor's residual claim on the produce of industry is determined by the deduction of the landlord for rent determined by the no-rent lands and by the profit of the employer as determined by the no-profit class. Obviously, therefore, everything that increases the produce of agricultural lands and contracts the circle of no-rents lands; or that increases the produce of the mines and factories and reduces the ranks of the no-profit class of employers is directly in the interest of labor. Although it would diminish the profits of some very successful employers at some times, they too would gain on the whole, for they would utilize their plants more fully and more steadily and while making smaller profits per unit of production would make more in the aggregate. In brief this is simply another expression of the gospel that it is to the interest of everybody to produce the most goods that can be produced. It is not money, or money-wages, that people want, although unfortunately that is what most of them erroneously think they want; but what they really want is the goods for which money can be exchanged.

If I should extend my remarks under the title of 'Industrial Co-operation', which, of course, is broad enough, to include co-operation by labor itself, I should put that at the head of everything, but while the eradication of its unfortunate delusions is not hopeless they are undoubtedly so deep-seated that any conversion to sound thinking will necessarily be slow. The laborer must be shown, and of course they can be, that by sound economic theory labor is the residual claimant upon the produce of industry; that its residual claim in America is 70 to 80% of the whole; that statistics prove that it gets it; that they show that when mind increases the produce of mere manual labor the latter gets the major part of the increment; that of the part of the produce of industry that they do not get they cannot get by any economic means; that in trying to get it by confiscatory means they not only do not get it but also lose more or less of what they were previously getting as their residual share; that the only way they can get any more than they do now is to produce more; that slacking in any form, either by working full time at only partial efficiency, or by working only part of the time of the week is directly opposed to their own interest, and that they are greater sufferers thereby than anybody else. "The day when labor exerts its full energy," says Sir Charles Allom, "it will inherit the greatest dividend in the world," and he adds, "Never did laborers exhibit less judgment in disturbing employers than in their selection of this moment. If they are left workless it will be their just desert."

But to instill these truths, while the minds are filled with fallacies of Karl Marx, which are so gross that they have been dismissed by the intellectual socialists themselves, will be slow, and the crisis into which the world has entered will not await an educational movement among the masses. Therefore must we appeal to the directive factors in industry and urge upon them the exertion of new effort to produce more, and as a means toward that end I advocate industrial co-operation, and thinking in terms of industries as a whole. In the program that I have outlined herein it will be perceived that the arrangement of cartels or commercial agreements other than what are based on sound economic grounds plays no part. Anything that is founded on the idea of restricting production or interfering with the free play of competition would be the antithesis of my thought. Nor does my program comprise the co-operation of labor, not that it would be unwelcome, but rather that it is not foreseen that it can be won. The only co-operation by labor that would be worth anything is the common sense kind. The talk about industrial democracy is clap trap and does a lot of harm. It is mischievous when one of our leading newspapers writes editorially like the following:

"Let us recognize the truth that the autocracy of capital is coming to an end. Nobody more clearly recognizes this than the autocratic capitalists themselves. At least, the more intelligent among them have their eyes wide open to what is going on. They have fully made up their minds that a larger share of the new wealth produced is to go to the men and women who contribute the labor that enters into its production. They have also made up their minds that heavier taxation of rich men has come to stay. More important than this, they have come to see that plans for developing industry are hollow which do not provide for the willing co-operation and interest of workingmen. No one is more eager to accept and apply sensible schemes of that sort than the fully wide-awake among the employing capitalists."

What is, or ever was, the "autocracy of capital?" It sounds bad, but it does not mean anything. Substitute the "authority of the directing minds" and we shall come nearer to the truth. Diminish that authority in any way and production also will diminish, and the men and women who labor will not be thankful. No larger share of the new wealth is to go to them unless they themselves make it larger by their own efforts, or what is more likely, unless it be made larger by new efforts of the directing minds whose authority it is sought to curtail. Heavier taxation of rich men may have come to stay, but that in itself is going to be to the detriment of the men and women who contribute the labor that enters into production.

If industrial democracy means merely the improvement of working conditions, and listening for advice about it from the men and women who work, by all means let us have it; but who has that simple conception of the meaning of the phrase? Employers ought to provide proper working-places, they ought to make them safe and light and sanitary for the sound reason that thereby they will increase efficiency. For the same reason they ought to provide compensation for sickness and accidents, old-age pensions, and in general should take care of their people. But the more enlightened employers already do this to a more or less degree, perhaps not enough, but nevertheless progress in this direction has been steady. All of this falls, however, under the head of industrial co-operation, which may be urged in every possible direction that is economically sound. The jargon "industrial democracy" is simply an expression of the discredited theory of Karl Marx, repudiated by socialists themselves, who recognize in the words of Mallock, that "in any complex system of industry, such as that which prevails today, the efficiency of the workers as a whole is the average efficiencies of the many multiplied by the efficiencies of the few," the Few being "the natural monopolists of ability," whose function is to issue orders, while that of the Many is to execute them with strict obedience. I may well conclude this paper with Mallock's own concluding words in his great book on 'The Limits of Pure Democracy', to wit: "In any great and civilized State *Democracy only knows itself through the co-operation of oligarchy*, or that the many can prosper only through the participation in benefits which, in the way alike of material comfort, opportunity, culture, and social freedom, would be possible for no one unless the many submitted themselves to the influence or authority of the super-capable few."

Economies in Hand Drill-Steel

This subject was discussed by H. A. Read, of the Rand Mines Limited, before the Chemical, Metallurgical and Mining Society of South Africa.

During the five years ended with 1917 the issues of steel per native had a value of £310,250 ($1,480,000), or an average of 86 lb., and $6.60 in value per native per annum. Consideration of the large sums involved in these issues of steel led to examination of the losses in detail. It appeared that one of the principal losses was due to the shanking of the steel under the blows of the hammer; this in turn led to the conclusion that if shanking losses could be prevented by means of a permanent drill-head, an appreciable economy would be effected. After some experimenting, the problem was solved. It was ascertained that by heating the end of the drill and staying it up (either by means of a die and dolly in a Leyner press or by hand) so as to give the head of the drill a bulbous or pear shape and subsequently tempering it, the drill would be provided with a head capable of resisting hammer blows without shanking. The question will be asked why the new form of drill-head stands up to the work. The explanation appears to be that the head is so stayed-up that the least possible disturbance is created in the molecular formation of the steel. Correct draw tempering then clothes the bulbous-shaped head with a fine coating of hard-tempered steel—probably not much more than $\frac{1}{16}$ in. thick, below which is a body of low-tempered steel. This latter metal (increased as it is beyond the original section of the drill) provides a reinforcement that prevents the disturbance and disintegration of the molecules of metal, which otherwise take place under impact of the hammer. The advantages of the new form of drill-head are as follows: (1) The saving of steel by preventing crushing or 'mushrooming' of the shank end; (2) elimination of danger to miners, as there are no splinters or jagged ends; (3) improved drilling, as the natives have a uniform tempered surface to strike, and the energy hitherto absorbed in shanking is diverted to the work of drilling; (4) improved control of steel; (5) the drill, instead of being a ragged-ended piece of steel becomes a tool well suited for the job; (6) the cost of trimming up and periodic re-tempering of the old form of drill by lead bath or other method (where such is the practice) is saved. The drill-heads are practically permanent, and, as the starter becomes too short, they may be welded onto other steel.

Mr. Read gave results of experiments carried out with this new type of drill at the East Rand Proprietary and Ferreira Deep mines. The conclusions derived were briefly: (1) The loss of steel hitherto sustained by the mines through mushrooming or crushing can be entirely prevented by the new permanent head; (2) a simple system of steel control can be introduced which will eliminate the heavy losses of hand drill-steel from causes other than fair and proper wear and tear; (3) the consumption of hand drill-steel can then be reduced to the amount of steel actually used in the processes of drilling and sharpening; (4) accidents and lost shifts hitherto caused by splintering of drills can be practically eliminated by the use of the permanent head; (5) there is evidence of an appreciable improvement in efficiency when using the permanent drill-head, as the energy hitherto absorbed in the crushing up or mushrooming of the shank is available for drilling; (6) the importance of the foregoing to the mining industry lies in the fact that the work of a large number of natives (averaging 45,000 per annum) is beneficially affected; (7) there is a field for further investigation in losses during sharpening and designing a suitable hammer.

The English-Speaking Peoples

By T. A. RICKARD

*We rejoice that the world-war is ended. We are proud of the part played by the English-speaking peoples—all doing equal honor to the traditions they share in common. One of the compensations for the calamity of the past four years is the fact that the Briton and the American, striving together in the cause of human liberty, have learned to understand and to respect each other. The mother country entered the fight resolutely at the beginning, while yet unready to meet the carefully prepared onslaught of the enemy; then the sons from the overseas dominions rallied to the old battle-cry eagerly and effectively; and last, but not least, the stepsons came from across the Atlantic, speaking the same speech, playing the same game, and fighting in the same clean way.

It was a great foregathering of those that use the language of Shakespeare and idealize the principles of liberty for which the friends and associates of Shakespeare stood sponsor three centuries ago.[1] At a time like this it is pleasant to dwell upon the fact that the liberal Englishmen who organized the Virginia Company were the pioneers of self-government on the American continent. The Virginia Assembly, convoked in 1619, was the first example of a domestic parliament to regulate internal affairs on this side of the Atlantic.[2] The Governor of Virginia, Sir Edwin Sandys, had been a pupil of Richard Hooker at Oxford and from that political teacher he and his friends had imbibed the idea of combining civil liberty with constitutional order. To this group of large-minded Englishmen the American colonists owed their liberal charters and their successive triumphs over the royal prerogative. Let it be noted that the American colonists had to deal with James II and George III, the two smallest minds in the list of British kings. Another historical note, more pleasant to record, is the connection between the two principal groups of American settlers. In 1608 when the Pilgrim fathers, William Brewster and John Robinson, led their Separatist congregation to Holland and there prepared the expedition to America, they were assisted by Sandys and the Virginia Council, who were willing to share their privileges with them. When the Pilgrims set sail in 1620 they had the promise, obtained by Sandys from King James, that they should have freedom of worship, equality before the law, and the right to participate in the government of themselves. Thus the men whom we may regard as the friends of Shakespeare aided the founders of New England. Together they resisted the King's arbitrary dictation. "The political principles that inspired . . that noble company never died out of Virginia, never died out of the northern colony, called New England. These were the principles first logically developed and clearly formulated by the tutor of Sir Edwin Sandys, Richard Hooker. Disciples of Hooker, associates of Shakespeare, were the founders of the first republics in the New World."[3] These political doctrines of Hooker not only inspired the founders of the first English settlements in America, but found an echo in the minds of the men who led the Revolution and subscribed to the Declaration of Independence. Hooker's ideas passed to John Locke, and through him to Benjamin Franklin, Patrick Henry, and Thomas Jefferson.

It seems worth while to make this point insistently. The old Fourth of July talk is out of date, because it is historically untrue. George III was born of German parents and married a German woman. He spoke Shakespeare's language with a guttural accent. His government failed to impose its tyrannic orders on the British colonists in America because it was not supported by the British people. Unable to conscript a British army, he hired the Hessians. It was against the forces of a reactionary German king that a great Englishman, George Washington, led his men to the winning of their independence. Lafayette and Rochambeau brought French aid to the revolutionists, but their help was prompted less by love of the colonists than by the desire to hit at England, which was then at war with France. It was the despotism of Louis XVI that sent Rochambeau and his 6000 Frenchmen "to deal England a blow where she would feel it." That was in 1780. Permit me to remind you that only 18 years afterward, in 1798, the young United States was at war with France. This is not mentioned out of ill-will, but as a historic fact of some significance. We need not belittle the romance of the Lafayette episode, even though it has been highly colored, because it is helping today to stimulate cordiality between the United States and France, but we may demur to the twisting of history in order to represent the English people as reactionary and the French people as liberal at the time of the American revolution. As one who holds that "every man has two countries, his own and France," as one that held this view even in the days of Fashoda, I venture to say that the friendship now existing between the United States and France is all to the

---

*An address delivered before the joint session of the American Institute of Mining Engineers and the Canadian Mining Institute at New York on February 17, 1919.

good, because England and France likewise are firm friends. Their *entente cordiale* joins with French-American sympathy in establishing a mutuality of goodwill between the three great democracies of the world.

It remains to emphasize another fact, to which allusion has been made already, namely, that the English striving for political freedom prepared the way alike for American and for French democracy. Locke, whose doctrines fed the fires of the English revolution of 1688 and those of the American revolution of 1775, derived his ideas of constitutional liberty from his fellow-countryman, Hooker. It was Locke's theory that was embodied in the American Declaration of Independence in 1776 and that rationalized the French Declaration of the Rights of Man in 1789. Rousseau exercised no influence on the America of 1776; on the contrary, it was from English philosophers and from Anglo-American reformers that the French revolution took its cue. English liberalism, disciplined by centuries of conflict, from the Magna Charta to the Bill of Rights, was the political mother of democratic institutions in the free commonwealths of the world.

Much of the prejudice against England inherited by children in the United States is due to the unfriendly tradition perpetuated in their school-books. Great Britain did treat the colonists shabbily after they had broken away from the old country, and, as the history of this nation is concerned chiefly with those early events, it is not surprising that the young American should be impressed much more by the overbearing attitude of Lord North's government, which was not so very different from that of most governments in those days, than by the shabby treatment given, in turn, to the loyalists in the American colonies. The so-called War of 1812 was bound to loom large in the school-histories, because it was the first contest following the achievement of American independence; but it was a tempest in a teapot; on land it was badly fought on both sides, although at sea the young American proved himself a chip of the old block; it was a side-show started in the midst of England's great contest with Napoleonic France. At that time England had a navy many times bigger than the American, and Wellington had just returned home from his victorious Peninsular campaign at the head of 100,000 veterans—a big army in those days. In 1814 Napoleon had been defeated, yet it was Wellington that made himself responsible for an honorable peace with the United States. It must be remembered that to the United States the Revolution was the very beginning of things; to England it was only one incident in a long and eventful history. "The game was played, and she had lost. North America, in the eyes of her statesmen, was a strip of eastern seaboard; the great lakes were but dimly understood; the continent beyond the Mississippi was ignored."[4] Therefore the Revolution and the little war of 1812 left no such sting in the minds of the British as the memories that were cherished on this side of the Atlantic. It is worth noting that in 1788 the first English settlement was made in Australia, at Paramatta, in New South Wales. Thus Australia was added to the British dominions at the time of the American secession.

Another thought follows: looking back, it is probable that if England had been minded to recover the American colonies during the early period of their independence, she could have done so; but she had no mind to do so, and any Hanoverian king or government that had tried it would have had to face a revolution at home. Moreover, it is quite certain that the United States would have seceded sooner or later, because no government in Europe could have hoped to retain control over the growing giant of the West. I am frank to add that the idea of filling the United States with Englishmen is as unwelcome to my taste as the idea of peopling the British Isles with Americans. Variety is the spice of life.

> "Our dearest bond is this,
> Not like to like, but like in difference,
> Distinct in individualities."

Let us hope that the school-room histories in America will be re-written in a spirit less unfriendly to the mother country. It may be more than a coincidence that the names of some of the publishers should be, for example, Kruger, Koch, and Lemp. When a New Englander or a son of Old England hears Germans, Irish, and Finns talking loudly about the time when "We licked the British in 1812," he may be pardoned for smiling. There were more Germans and Irish on the reactionary side in 1812 than on the liberal side. An acquaintance of mine, an Austrian Jew, the editor of a Jewish paper in San Francisco, began to tell me about the time when "*We* licked the British," whereupon I called a halt and asked him *qu'allait-il faire dans cette galère?* I informed him that I had ancestors on both sides of that affair, at a time when his progenitors were wandering in the morasses of Eastern Europe without even a knowledge of the fact that the British were having a family quarrel. The foregoing story is capped by the statement appearing in a pamphlet prepared by the Sinn Feiners and intended for propaganda among the American soldiers stationed in Ireland. "We helped to win your independence," they assert.[5] The forefathers of this Republic may have had some outside help, but it is a little hard on them that they should be called upon at this late date to divide the honors with such as the Sinn Feiners. The people *they* helped were the Germans, not in 1776, but in 1917.

A couple of stories will illustrate this point further. During the Spanish war of 1898 I had as neighbors a man and his wife of British birth, but of American citizenship. One day the man, in the presence of his son, a boy 12 years old, remarked that the United States would defeat Spain. Whereupon the boy exclaimed: "Lick Spain, well I guess we will! Why we licked *you* twice!" That boy and his two brothers have fought side by side with the British in France, one of them wearing the uniform of his father's native land, because he could not wait until his own country entered the war.

---

[4] F. S. Oliver in 'Alexander Hamilton'. Page 115.

[5] As recorded in despatches published on January 11, 1918.

Another boy's historical knowledge concerning the relations between the United States and Great Britain consisted of three items:

(1) Major Pitcairn spoke contemptuously of the revolutionists while he stirred his punch at Lexington.

(2) Andrew Jackson refused to black the dirty boots of a British tyrant.

(3) The Americans licked the English twice, and would do it again for two cents.

Yet it is recorded that this same boy knocked down a perfectly well-behaved Bavarian in a barber-shop for expressing the opinion that England would be invaded. You could tell that boy all you pleased about the battle of Bunker Hill and the villainy of Lord North, but he would not forego his share of ownership in the Black Watch at Waterloo, of Nelson at Trafalgar, of Wolfe on the heights of Quebec, of Drake and the 'Golden Hind', or of the archers at Agincourt.

The tale of an ancient wrong should now be laid aside on a shelf beyond the reach of any but the most inquisitive student. The memory of Bunker Hill is overlaid by that of Manila Bay. Let me recall the story as recorded by Dewey himself.

When Commodore Dewey drew the attention of Vice-Admiral von Diedrichs to the disproportion between the German naval force at Manila and the German interests in the Philippines,[6] he was met with: "I am here by order of the Kaiser, sir." The German admiral made trouble for the Americans continually, while maintaining the most cordial terms with the Spaniards; this also, it is to be presumed, by order of the Kaiser. He repeatedly ignored the blockade that Dewey had established after the battle of Manila Bay, sending his warships into the harbor without allowing them to be boarded, as was necessary in order that they might be identified and assigned an anchorage. Dewey, in his autobiography, says: "Vice-Admiral von Diedrichs, in denial of the right, had notified us that he would submit the point to a conference of all the senior officers of the men-of-war in the harbor. But only one officer appeared, Captain Chichester, of the British 'Immortalité.' He informed the German commander that I was acting entirely within my right; that he had instructions from his government to comply with even more rigorous restrictions than I had laid down; and, moreover, that as senior British officer present he had passed the word that all British men-of-war upon entering the harbor should first report to me and fully satisfy any inquiries on my part before proceeding to the anchorage of the foreign fleet."[7]

It is related by General Younghusband, of the British army, who was at Manila at the time, that when Von Diedrichs asked Chichester what he intended to do, the Englishman replied: "Just what Admiral Dewey and I have agreed upon."

A more significant incident occurred later, just before the town of Manila was captured, on May 13. I quote Dewey again: "As we got under way the officers and men of the British ship 'Immortalité' crowded on the deck, her guard was paraded, and her band played 'Under the Double Eagle,' which was known to be my favorite march. Then, as we drew away from the anchorage from which for over three months we had watched the city and bay, Captain Chichester got under way also, and with the 'Immortalité' and the 'Iphigenia' steamed over toward the city and took up a position which placed his vessels between ours and those of the foreign fleet."[8] Thus the British warships were differentiated from the "foreign" fleet; they stood between Dewey and the Germans.

This was no mere idiosyncrasy of Chichester; it expressed the policy of the British government. In March 1898 Germany asked England to join her and France in putting their fleets between Cuba and the American fleet. The British Foreign Secretary promptly refused. Great Britain was the one power that prevented the formation of a European coalition against the United States at the time of the war with Spain. It was then that the Kaiser exclaimed: "If I had a larger fleet I would take Uncle Sam by the scruff of the neck." More recently that part of his own anatomy his been in acute danger. On May 11, 1898, while the Spanish-American war was in progress, Joseph Chamberlain, the Secretary of State for the Colonies, said in a speech at Birmingham:

"What is our next duty? It is to establish and to maintain bonds of permanent amity with our kinsmen across the Atlantic. There is a powerful and a generous nation. They speak our language. They are bred of our race. Their laws, their literature, their standpoint upon every question are the same as ours. Their feelings, their interests in the cause of humanity and the peaceful development of the world are identical with ours. I don't know what the future has in store for us; I don't know what arrangements may be possible with us; but this I do know and feel, that the closer, the more cordial, the fuller, and the more definite these arrangements are, with the consent of both peoples, the better it will be for both and for the world—and I even go so far as to say that, terrible as war may be, even war itself would be cheaply purchased if, in a great and noble cause, the Stars and Stripes and the Union Jack should wave together over an Anglo-Saxon alliance."

Therein Chamberlain exhibited not only a brotherly spirit, but also the highest quality of statesmanship—foresight. His hope was fulfilled in 1918.

The echoes of Yorktown and Saratoga are smothered by the glad shouts that come from Belleau Wood, Cambrai, Lille, and other recent battlefields on which the Union Jack and Old Glory were carried forward to victory. Then was fulfilled Jefferson's hope, as expressed in a letter to President Monroe, in 1824, advising him to accept the policy, now known as the Monroe doctrine, which had been suggested by George Canning, Secretary of Foreign Affairs for Great Britain. Thomas Jefferson wrote "Great Britain is the one nation which can do us the most harm of anyone, or all on earth; and with her on our side we need not fear the whole world. With her then, we should sedulously cherish a cordial friendship, and nothing would tend more to knit our affections than to be fighting once more, side by side, in the same cause." That pious wish, so like Chamberlain's, has been splendidly fulfilled. Do you remember one of the flashes of history that we found in the day's news last October? It ran something like this:

---

[6] 'Autobiography of George Dewey, Admiral of the Navy', 1913. Page 257.

[7] Op. cit. Page 266.

[8] Op. cit. Page 277.

Somewhere on the Western front an assault was launched at dawn under cover of a creeping curtain of shell-fire. An American division advanced shouting 'Lusitania.' With them went a squadron of tanks. While this attack was progressing favorably, a British division on the left swam the canal and pushed forward, in the face of scores of German machine-guns, to the village of Bellеglise. By nine o'clock prisoners were being sent to the rear in droves. A pause followed this first phase of the battle. The Americans, tired, but elated, stood in the trenches they had captured, while an Australian regiment, moving to their support, passed over them, or 'leap-frogged,' to form the first wave of a new advance. The storm of cheering that greeted this maneuvre rose high above the din of battle.

We echo those cheers today. The word 'Lusitania' made those English-speaking soldiers a unit against

"A people with the heart of beasts
Made wise concerning men."

One fateful consequence of the War is the suicide of the German tradition. Before 1914 the Germans had a growing hold upon American business, they were grafting their kultur upon the American people, chiefly through the scheme of exchange-professors, whereby German propagandists were given a free hand at American universities, and, what was worse, sundry American professors went to Berlin, where they succumbed to the hospitality of the Kaiser and became sycophants to his purpose. The Germans were even obtaining success in imposing their language upon a large number of native-born Americans; and in doing this, they were undermining the English tradition, inherited legitimately from the founders of the United States. They were assisted in their propaganda by the fact that many Germans of the highest character migrated to the United States at the time of the War of Liberation in 1848. These proved excellent American citizens because they came mostly from the South German States and brought with them none of the Prussian idea. They were followed in later years by other Germans, not so liberal-minded, but of undoubted capacity in business. Clannish always, they co-operated, they became pioneers of the German idea, which had made considerable headway when William of Hohenzollern and his military caste, supported by the German people, began their onslaught upon Western civilization. During the time the German tradition waxed in the United States that of the mother country waned; for many reasons, some large, others small. The American alienation from the people of "the sceptred isle" has been due in part to sympathy for those of "the emerald isle." Undoubtedly the blundering policy of the British government in handling the Irish question has tended to perpetuate the prejudice against England; the Irish are born politicians; in the big cities of this country they exert an influence far out of proportion to their numbers or their character; they have played into the hands of the Germans and together they have fostered a sentiment that has tended continually to hinder the development of goodwill between our peoples. By "our peoples" I mean those represented by the Canadian Mining Institute and the American Institute of Mining Engineers. For generations it has been the popular thing in the United States "to twist the lion's tail"; it pleased both Irish and American prejudice; it was the regular stock-in-trade of frothy orators and jingo editors.

The English-speaking peoples have so many proud and happy memories in common that it is about time to balance the account. England did treat the colonists arbitrarily, and they treated the loyalists meanly; the young United States soon after achieving independence did have a further fuss with the mother country, which withdrew from the quarrel voluntarily. So much for that. From her independent sons in America, England learned a lesson she has never forgotten, as is proved by the record of her relations with Canada, Australia, India, and Egypt, and her other territories, particularly her treatment of the Boers. She holds her overseas dominions by the silken thread of goodwill, by that and nothing more. The American people shares with the English people the glorious traditions derived from the men that helped to develop constitutional liberty before the Declaration of Independence, which was a logical sequel to the Magna Charta and the Bill of Rights. Many Americans, even those of British descent, may choose to forego the privilege of sharing those ancient glories, but they will not refuse to claim the inheritance of Chaucer and Spenser, of Shakespeare and Milton, of the King James version of the Bible and the Book of Common Prayer, of the English common law and the unwritten rules whereby both alike 'play the game' in war and peace. For those traditions we are joint trustees. To them we add now the vivid, the searing, the proud memories of the Great War, in which at last our men stood shoulder to shoulder to assert the principles of freedom on earth. Abraham Lincoln closed his first inaugural address by an appeal for reconciliation with the South: "The mystic chords of memory, stretching from every battlefield and patriot grave to every living heart and hearthstone all over this broad land, will yet swell the chorus of the Union, when again touched, as they surely will be, by the better angels of our nature." Does not this find an echo in our hearts today; do not the chords of our memory vibrate to the stories that have come from the battlefields in France, and will not the better angels of our nature play on those mystic chords a song to which we can pull together in unison for liberty, justice, and peace?

The visit of President Wilson to England, following our comradeship in arms during the War, is one of the great events of history. The intensely cordial greeting that he received during his visit, not only from King George, but from the crowd, augurs well for the friendship between the English-speaking peoples. One of our miserable San Francisco papers spoke of the reception accorded to the President as the most enthusiastic ever given to "a foreign citizen," as if a man who found himself in a country where his native tongue is spoken, where his mother was born, and from which his paternal grandfather came, could feel himself a 'foreigner.' Legally he may be, but setting aside the legal fiction, Mr. Wilson found himself among his own kinsmen. There are three kinds of people in the world: Americans, Britons, and foreigners. Does any one of us feel like a foreigner when he is either in Canada, England, or the United States? I trow not. However, I have lived so long in the United States that I venture to warn Britons against over-playing the 'kinsman' note. Mr. Wilson's ancestry brings him within the category, but most Americans do not like to be dubbed 'kinsmen' or 'cousins,' because they are strongly assertive of their nationality, and of their own identity as a people; moreover, the influx of alien blood from the other countries of Europe is so considerable that it is incorrect to regard the American as a cousin of the Briton. Indeed, this assumption was at the bottom of much of the chagrin felt in Great Britain and in Canada when the Government of the United States deliberately adopted an attitude of neutrality during the early part of the War. Impatient as most of us may have been at the aloofness of the United States during that period, we should have reminded ourselves that the American people includes a large proportion of citizens of other than British descent, about one half, of whom ten millions were born in Germany or born of German parents, and perhaps twice as many more have German ancestry. We ought to have reminded ourselves that even those who are of British descent feel their separateness strongly, partly on account of old revolutionary prejudice, and partly because there is that constant urge to emphasize the individuality of the American nation. That is why I deem it more tactful, and also more in accord with the facts, to lay stress on our common notions of fair play and our common insistence on the right to live and let live—the right that the Prussian and his cohorts undertook to suppress. The Briton must accept the fact that the American, especially those Americans who have no English blood in their veins, dislike an excess of emphasis on kinship. For instance, Theodore Roosevelt objected to it, and he was a typical American if ever there was one. He had Dutch blood, English blood, French blood, even German blood, in his veins, but there is no mistaking the fact that in him it was no mere mechanical mixture, but an ethnical compound, called 'American', because it is entirely different from any of the ingredients of which it is composed. As he himself said: "We are a new and distinct nationality. We are developing our own distinctive culture and civilization, and the worth of this civilization will largely depend upon our determination to keep it distinctively our own." That undoubtedly is the voice of young America, the expression of the virile nationalism that Roosevelt typified so splendidly. If the call of the blood were to be taken literally, the cries from America to Europe would be as confused as those which arose from the Tower of Babel. President Poincare at the opening of the Peace Conference said appropriately: "America, the daughter of *Europe*, crossed the ocean to rescue her mother from thraldom and to save civilization." Therefore it is wiser to base our international friendship upon the other factors: language, literature, law, sports, ideas, and ideals, themselves largely a consequence of our common ancestry.

Our peoples differ in their traditions and also in their outlook, or, to be more nearly correct, the Briton cares more for tradition than the American, who, on the other hand, cares more for outlook. The one feels his background, the other his foreground. The Englishman accepts his social environment; he is proud that his father and grandfather did as he is doing; he loves the continuity of custom. The aim of the American is social extrication; he sees no reason for following in the footsteps of his forbears; he blazes a fresh trail, and rejoices in breaking into a new environment. Britain is politically a democracy, but socially she still preserves many of the traditions of feudal days. These make for the amenities of life, but they, and the social manners derived from them, are distasteful to the unconventional men and women of a country that has broken definitely with all that such customs imply. To us, "the rank is but the guinea-stamp; the man's the gold for all that." In freeing ourselves from such trappings we may have gone to the other extreme; the lack of respect for authority is not the most desirable trait of the democrat.

Life is full of compensations; every loss has some gain. The engaging frankness of the American contrasts with the starving of emotion in the Englishman. He thinks it good form to suppress any expression of enthusiasm to the point of making himself appear cold or supercilious. It is an unlovely trait and destroys the natural grace of an intelligent human being. In England the religion of 'good form' is a disease among well-bred men, making spontaneity a mark of the socially uneducated. An American officer says to a British officer: "Well, I guess we'll have to clean up the Boches together!" The English officer, adjusting his eye-glass, says, "Really." That reply was not meant to be insulting, but it chilled any *rapprochement*. We are reminded thereby of "a certain condescension among foreigners," on which an American essayist expatiated. May I suggest that some of the British superciliousness is due to shyness, not to impertinence; it is what our French friends call *mauvaise honte*; it springs from the Englishman's inbred fear of making himself ridiculous. On the other hand, the autobiographical garrulity of an opposite kind of American and the boyish inquisitiveness with which he will dive into the affairs of a comparative stranger bear the marks of a crudity that may sometimes be repellant. Again, an Englishman will be severely critical of his own country, because to him to speak well of her is like speaking well of himself, which is taboo, whereas the American will sail in boyishly to praise his native country, and to assert how superior it is to every other. Such small national differences should be taken with good humor. The social code of a small island 3000 miles away does not fit the less formal, more spontaneous, life of a younger people sprawling across a continent more than 3000 miles wide. The American ought to understand the Briton if anybody is to do so, and, conversely, the Briton ought to meet the American half-way quicker than anybody else. Our mannerisms may be different, but our ideals are much the same. I am reminded of the story told of the judges who were preparing a congratulatory address for presentation to Queen Victoria, on the occasion of her jubilee. They were discussing the phrase "conscious as we are of our many infirmities," whereupon Bowen, the Master of the Rolls, suggested that the wording should be changed to "conscious as we are of each other's many infirmities." That, I regret to think, is what we do internationally. We are too much like the old man who said to his wife: "Everybody is queer except thee and me, and sometimes I think thee's a bit off." We need more tolerance—a more tolerant humor—remembering that a friend is a man whom you know well and still like. Britons and Americans can risk the closer acquaintance that leads to friendship, because they have fewer divergencies than common aims; and their friendship will be on a safer footing if they take each other as they are and determine to make the best of their interesting differences.

Let us look forward instead of backward. Whatever our differences in the past, let us realize the similarity of our aims, the identity of our political ideals, and endeavor so to act and speak that the harvest of this calamitous war shall be not the barren thistle of discord but the wholesome wheat of goodwill. The great sacrifices entailed by the War will be inadequately compensated if the result is not to establish closer relations of friendship between Britain and America. Indeed, it would be an immeasurable loss if the peace settlement should provoke any discord between the two English-speaking peoples. If we cannot agree to keep the peace, nay more, to work for human progress together, then no league of nations is conceivable that will do so. On the contrary, if there be any hope that mankind will advance not only from a jungle existence but from the organized vendetta of a semi-civilized state of society, if there be any hope of improvement in national relations, then that hope lies in one fact—a fact of which we have common reason for being intensely proud—and that is the 3500 miles of unfortified frontier between Canada and the United States. If we can live on such terms, with a willingness not only to arbitrate international differences but with a constant desire not to provoke them, then other nations—in time, all the nations of the world—will find it desirable, will find it imperative, to do the same. Let that physical frontier, without the menace of a fort, without the provocation of a single cannon, be the symbol of unaggressive neighborliness, of a mutual goodwill, of a promise of that "far off divine event"—of universal peace and amity—"to which the whole creation moves."

Flotation of Native Sulphur Ores

By JAMES M. HYDE

[*]The object of this investigation was not to work out the best practice for any particular ore, but to determine how generally concentration by flotation may be applied to sulphur ores, and what may be expected from its use. A summary of results follows:

1. All sulphur ores so far tested by flotation yielded promising results.

2. The ores from several districts can be treated successfully if suitable water is available. Under favorable conditions, better than 80% of the sulphur should be recoverable as concentrate containing more than 80% sulphur. Much higher results may be obtained.

3. It is possible to make high-grade brimstone direct by flotation on at least one ore, and also by refining concentrate.

4. The concentrate appears to be suitable for many purposes for which high-grade sulphur is now used.

5. In addition to the demand for sulphur that previously existed, an ever-increasing demand for sulphur as a soil-dressing may be expected, and this should eventually consume a large quantity. Flotation concentrate will be especially suitable for this purpose.

6. Raw sulphur and raw phosphate rock may be used for the commercial manufacture of acid-phosphate fertilizer. Flotation concentrate should be especially suitable for this purpose.

The flotative agents so far used included pine oils, or creosotes, No. 80 and 350, from the Pensacola Tar & Turpentine Co., wood creosotes, No. 17 and 18, from the General Naval Stores Co., ore separation oil No. 1, from the Standard Oil Co., kerosene from the laboratory supply, cresylic acid No. 206, carbolic creosote No. 158, coal-tar creosote No. 118, and coal-tar No. 300 from the Hunter-Johnson Co. of San Francisco, wood creosote No. 1 and 2 from the Cleveland Cliffs Co., and mixtures of the above, amyl-alcohol, glycerin, and crude pyroligneous acid and sulphuric acid. All of these have been used with air in agitation and pneumatic flotation-test machines designed by me for my own use. Air without any other reagent save water has been used in both agitation and pneumatic flotation-test machines. With the exception of crude pyroligneous acid and glycerin, all of the reagents used facilitated the flotation of sulphur; but the results attained in the earlier tests led to the use of carbolic creosote No. 158, or a mixture of equal parts of kerosene and Pensacola No. 80, in most tests. These all gave satisfactory results.

---

[*] Abstract from Minerals Investigation Series, No. 15, U. S. Bureau of Mines, 1919.

REVIEW OF MINING

JOPLIN, MISSOURI

STATUS OF ZINC MINING IN THE TRI-STATE REGION

A study of the zinc industry of Missouri, Arkansas, Kansas, and Oklahoma during the past ten months: an address delivered by Otto Ruhl before the American Zinc Institute at St. Louis:

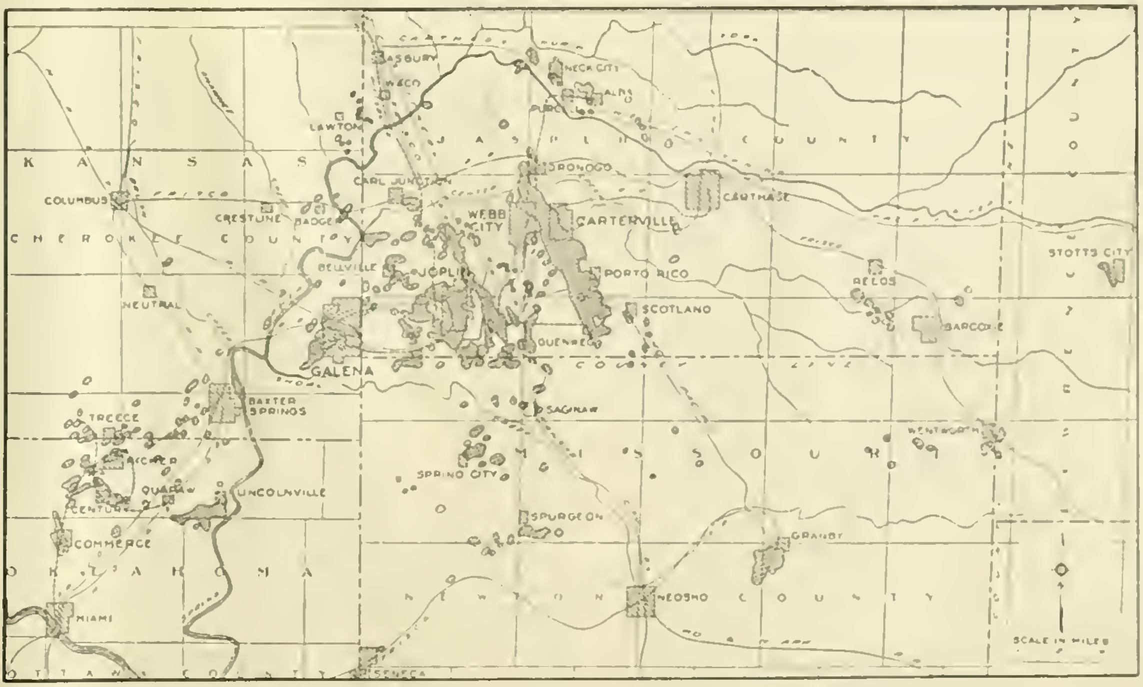
A review covering the last 10 months mining operation in the Joplin-Miami district is but a repetition of that given a year ago, with the exception that the lights have been fading, and the shades are deeper, so to speak.

Hard hit last year, the zinc-mining industry of the four States today is in even a worse state than then. In Missouri one can count the active milling plants practically on the fingers of two hands; Arkansas has but a negligible output of zinc ore today; Oklahoma and Kansas are supplying the bulk of the output. Singularly enough we find the efforts of the field to curtail its output but partly successful, a fact due to the gradual but inevitable fruition of prospecting efforts begun two years ago. It has been said, and truthfully so, that 10 years prospecting was done in the Oklahoma field in two years time. The results have been the development of a large number of mines whose output has been thrown on the market, and kept up the output of this district in the face of untoward price conditions to an unusual level. Much of this output is not the result of studied operation, but incidental to prospecting and development, and in most cases produced at a staggering loss. Yet the tonnage of these mines in the aggregate has maintained the output of the district at close to 10,000 tons per week. It is difficult to reconcile this heavy production with the fact generally known as to prices for ores, and with the fact that so many mills are closed down. A census taken of the mills of the field within the past month showed out of 208, a total of but 58 operating, or approximately 28% of the potential producers. With these 58, however, the bulk of the tried operators and the low cost mills are found, a synonym for either high-class operation or extremely rich properties.

The following tables of shipments and prices for corresponding months of 1918 and 1919 show a consistent decline in prices received, but no such decline in output.

Comparative production all grades zinc ore 1918-'19, tons:

Month	1918	1919
January	32,995	27,102
February	22,250	40,228
March	47,955	50,851
April	45,810	36,890
May	44,315	47,570
	194,325	202,059
Surplus on hand	27,500	16,000
	221,825	218,059



MAP OF AREAS THAT HAVE PRODUCED ZINC AND LEAD IN THE TRI-STATE REGION

Comparative zinc-ore prices 1918-'19, per ton:

	1918		1919	
Month	Blende	Calamine	Blende	Calamine
January	$57.02	$32.67	$43.41	$35.01
February	55.00	33.00	41.78	26.27
March	50.14	34.73	41.54	27.74
April	42.03	32.93	38.87	20.61
May	47.70	31.00	37.80	24.80

Compared with 1918, the 1919 period shows an average reduction of $11.89 for blende ore and $3.06 for calamine ore.

One would naturally anticipate that the reason for this condition must be explained by greatly reduced cost of operation. While there have been some reductions in costs, they have not been commensurate with the reduction in prices received for the product. The reductions in the former have been approximately 10% in labor and a small reduction in hard iron and powder. Other costs either have been maintained or actually advanced as in the case of power and lubricants. A reduction in one class of supplies is practically balanced by advances in others. It therefore becomes increasingly apparent that much of the output being maintained is produced at a loss. Recently, when the price of ore dropped to a $35 base, some of the very strongest operators in the field shut-down some of the best and richest properties, while weaker concerns and poorer properties can still be found desperately trying to keep going.

Under these conditions production of the field is approximately 9000 to 10,000 tons, and its potential production on a $45 to $55 market can be readily determined at 50 to 60% more. From this situation it is evident that Joplin operators are hoping for a hurried revival of zinc consumption and a greatly increased use for this metal.

The end of the War brought with it the end of all price agreements, and the co-operation between smelters and ore producers. The whole market situation reverted to the old open system where "everyone for himself and the devil take the hindmost." The co-operative action between the sheet-zinc manufacturers and the high-grade zinc ore producers, which was so satisfactory during the War, today is almost forgotten history and a similar movement to take care of all classes of ores and with all the smelters met a like fate before it was more than suggested. Certainly the industry needs such co-operation today as much if not more than during the War. But so far as one can now see, the inevitable law of the survival of the fittest must take its course, and only those with unusually rich deposits can survive the squeezing process of high production costs and low ore prices. How long this process must continue to bring about the extermination of the output, which will again balance local supply and demand, is difficult to answer.

It was pointed out at last years' meeting (of the Zinc Institute) that the "souls of operators were born, kissed by the enthralling rapture of eternal optimism." The past year's history is confirming evidence that they will endure impossible conditions and yet live. If they cannot produce ore for a profit they do it for philanthropy, and the world gets its zinc metal mined for less than cost.

The salient features of the year's history as reflected in the zinc-mining industry of Missouri, Kansas, Oklahoma, and Arkansas are:

1. That the production in Missouri and Arkansas has grown smaller since last year.

2. Output of Oklahoma and Kansas holds strongly at 9000 to 10,000 tons.

3. Production is maintained at a high level in spite of large numbers of mills closed down.

4. Only the richest ore deposits can be worked and the best organized companies can operate, and much of the ore is being produced at a loss.

5. Ore prices declined $11.89 per ton over last year, but this did not greatly reduce the output of ore.

6. Cost of production remains high, and changes in some items while lower have been balanced by others that have advanced.

7. End of war brought all price agreements to an end and no co-operative efforts since have been successful.

BISBEE, ARIZONA

PROGRESS AT SACRAMENTO HILL.—TOMBSTONE MARBLE DEPOSITS.

Removal of overburden from the Copper Queen's Sacramento hill in April was 176,000 cu. yd. This is a record. Although a little more than 2,000,000 yd. of capping waste has been removed so far, exposure of the ore for steam-shovels is only 40% complete. This work is one of the largest mining operations in Arizona at present. Eighty trainloads of waste are removed daily, and used in filling ravines and gulches throughout the Warren district. The Dallas shaft of the Copper Queen is to be enlarged from two to five compartments in the near future. The Calumet & Cochise is undergoing development, it being intended to sink below the 1500-ft. level.

What is expected to be one of the largest marble quarries in the United States is being opened by Bisbee and Los Angeles capital 15 miles from Tombstone in the Dragoon mountains, 4 miles from Dragoon station on the Southern Pacific railroad. The Dragoon Marble & Mining Co., as it is known, has 1600 acres. A. T. Kolb is president; J. S. McNeish is secretary; Robert Hennessy of Bisbee, L. H. Turner of Pasadena, and George Weifenbaugh of Los Angeles are directors. The last named owns a large finishing plant in Los Angeles and will handle the finished product for the company. Mr. Kolb, an experienced marble man, states that marble of almost every variety is to be found on the property. There are 20 varieties that can be used for building purposes.

D. C. Sweet and John Fahey of Hollywood have been at Tombstone to inspect mining property owned by Californian capital, which they represent. They have been examining the Brandt claims, known as the Free Coinage group, situated near the old State of Maine mine, in its day one of the largest producers of the district. A large vein of high-grade ore was opened recently, and development was to be started early in June.

JACKSON, CALIFORNIA

THE ARGONAUT, KENNEDY, OLD EUREKA, AND CENTRAL EUREKA.

Milling operations were resumed at the Argonaut mine on June 1, after a cessation of about two months. The fire discovered on the 4000-ft. level on March 27 is known to be burning still, but it is well under control, and strong bulkheads confine the fire to one level; this, fortunately, is not one on which the mill depends for ore. Mining and development are now under way both above and below the bulkheaded level. The odor of gas is plainly evident at all times in the vicinity of the Muldoon shaft, notwithstanding its being bulkheaded: the fire is known to be entirely on the Muldoon portion of the property, which accounts for miners working in safety in the Argonaut proper. About two weeks ago, one of the bulkheads failed and revived the fire, but this caused only a few days' delay, and 40 or more employees returned to work as soon as the bulkhead could be made tight; only a short time will elapse before the usual crew will be employed. The early return of this great mine to normal conditions means much to Amador county, as the Argonaut ordinarily employed over 200 men, and until the fire broke out, was one of the largest gold producers in the State. N. S. Kelsey is general manager of the property, which is equipped with a new 60-stamp mill and high-class electrically-driven machinery.

Aside from a cessation of mining for a few days when fume from the Argonaut mine penetrated the Kennedy workings, adjoining the Argonaut on the north, the Kennedy continued in full operation with its 100-stamp mill. Webb Smith is still in charge of this mine.

A station has been cut on the 3000-ft. level of the Old Eureka mine at Sutter Creek and shaft-sinking from a point nearly 100 ft. below this station will be resumed shortly. A large amount of development will be done from the 3000-ft. station, both north and south, to prove the existence on that level of the veins worked so profitably in the early days on levels nearer the surface. Low-grade ore in large quantities is exposed on the 1200, 1600, and 2100-ft. levels, ore that could be worked far more profitably by modern methods than was possible when the mine was last worked over 30 years ago. This factor and the opening of high-grade ore found since reopening the mine ensure the future success of the Old Eureka, and the discoveries at greater depth in the Central Eureka promise good things at similar depth for its neighbor. In addition to the expense incurred in equipping and unwatering the old mine to 2190 ft., formerly the deepest point, the new owners have enlarged the old shaft from one to three compartments from the 1600-ft. level down, and sunk the shaft nearly 1000 ft. additional. A great future is predicted for this old-time producer, after it has been sufficiently opened to warrant the erection of a mill. T. C. Gorrie is general manager, and Timothy Donovan is foreman. It is of interest to know that many of the enterprising men who have staked their money in the Old Eureka are also heavily interested in the Lincoln Gold Mining Co., which recently acquired the Wildman, Mahoney, and Lincoln mines, so that practically the same people own the mineral rights to a long stretch of the Mother Lode underlying the city of Sutter Creek.

Sinking at the rate of about 17 ft. per week continues at the Central Eureka mine, where the shaft has now reached a depth of 3720 ft. For 100 ft. or more, the shaft has been sunk in hard greenstone, but the contact slates have been reached. Progress will doubtless be better in this softer ground, until the point desired is reached. The present contractors are sinking the shaft 210 ft. at $31 per foot, this to cover cost of labor and explosives. The closing of this contract will mean a depth of nearly 275 ft. below the 3500-ft. station. The intention is to cut a large station at 3700 ft., and prospect from that point the good ore now being mined on the 3500-ft. level and the 3600-ft. or winze level, on which more than half of the mill is constantly employed while development work proceeds. A. S. Howe is superintendent and H. Warrington is assistant.

DULUTH, MINNESOTA

MEETING OF SAFETY ENGINEERS.

Managers, superintendents, and safety engineers numbering 100, according to the estimate of B. O. Pickard of the U. S. Bureau of Mines, were to gather at Duluth on June 19 and 20 for the first important district safety conference for metal mine officials ever held in the United States. Mr. Pickard, who is district mining engineer for the Bureau in the mining States adjoining Lake Superior, arranged this conference after observing the results of a similar meeting at Houghton a month ago, the latter being for upper Michigan peninsula safety-men only. The Duluth conference is for a discussion of safety problems affecting the copper mines of Michigan, iron mines of Michigan and Minnesota, and zinc mines of Wisconsin. A committee consisting of George Martinson of Gilbert, Minnesota; William Conibear of Ishpeming, Michigan; and Stephen Quayle of Virginia, Minnesota, had the program in hand. C. E. Julian, of the U. S. Bureau of Mines experiment station at the University of Minnesota, Minneapolis, will give a welfare talk. Other speakers and papers will be as follows:

'Statistics and Practical Forms for Accident Records', A. H. Fay, Bureau of Mines, Washington, D. C. 'Safety in Mining Stopes', M. E. Richards, general manager, Judson Mining Co., Crystal Falls, Michigan. 'Care and Welfare of Labor', C. K. Quinn, president Quinn mining interests, Minnesota. 'The True Meaning of 'Safety First',' A. K. Krogdahl, Virginia, Minnesota. 'Problems in the Work of Accident Prevention', William Cinibear, chief safety engineer, Cleveland Cliffs Iron Mining Co., Ishpeming, Michigan. 'Mine Fire and Accident Signals', B. O. Pickard. Other speakers were to discuss safety in open-pit mines, vocational schools for miners, safety organizations for mining companies, rehabilitation of injured miners, and kindred subjects.

PORCUPINE, ONTARIO

LABOR TROUBLES.—NEW POWER SCHEME.

The mining fields of northern Ontario are affected by the general unrest and dissatisfaction prevailing in nearly all industries, and demands for recognition of the union, increased pay, and shorter hours have been made by the miners of Cobalt, Porcupine, and Kirkland Lake. These have been coupled by threats of a walk-out; Cobalt miners are reported to have voted in favor of a strike. It is considered hardly likely that any serious trouble will result, as it appears that the movement will not be financially supported by the international union; moreover, the local union is by no means a strong body, as only about half of the mine employees are members. The Porcupine miners have declared against a strike, and the position at Kirkland Lake is still undecided.

Matachewan.—It is proposed to generate electric power for the field at Matachewan falls six miles north. Sutcliffe and Neelands, of New Liskeard, who have obtained permission from the Ontario government to develop the falls, have sold a half-interest to F. C. Sutherland & Co. of Toronto. The falls have a nearly vertical drop of 41 ft., rendering development a comparatively easy matter. At the Matachewan mine (formerly the Otisse) a rich lens of ore has been opened between the 50 and 100-ft. levels, showing much free gold.

West Shining Tree.—An option on the Foisey claims, which include ¾ mile of the Ribble vein, has been given to E. J. Longyear Co., of Minneapolis and Sudbury. The same firm recently took over the Bennett claim. Their entrance into this field is regarded as assuring that its value will be thoroughly tested.

GOLDFIELD, NEVADA

PREPARATORY WORK BY THE DEVELOPMENT COMPANY.—GRANDMA AND ATLANTA.

Enlarging and repairing of what will be made the main haulage-way in the Combination mine has been started by the Goldfield Development Co. The main drift used during operations by the Consolidated will be used for this purpose. The cross-cut from this drift to the shaft, through which all ore in the Combination will be hoisted, has been advanced 150 ft. or half-way to the shaft. The drift and cross-cut will not be double-tracked as at first planned, as the electric locomotive to be used will haul over 20 tons on each trip from the chutes, which is considered ample. Raises are being driven at 50 instead of 25-ft. intervals, as was at first planned, it being considered that there will be less inconvenience from timbers blocking the raises than was at first thought. The first half of each raise above the haulage-way will be vertical. At the top will be a grizzley and space for shovelers to move the material as it comes from the upper or inclined half of the raise, which will be driven into the vein-filling. The incline raises will be made of sufficient size for the timbers that will be drawn with the ore to pass through, and it is believed that little blasting will be necessary to ensure a continuous flow. The timbers will be lowered through a compartment in the vertical raise to the haulage-way. The hoisting plant formerly in use at the Mohawk has been erected at the shaft, and grading is being done for ore-bins and railroad track, 900 ft. of which will have to be moved a short distance, so as to have it extend parallel to the bins. The Red Top is being prepared so the ore to be mined there can all be hoisted from the first level of the Laguna shaft. The shrinkage system can be used in the Red Top, but it has been determined that in the Mohawk, where the vein is flatter, the handling of the material will be left to lessees for the present. The mining of stope-filling and low-grade ore in place in the Mohawk is believed to hold great possibilities, but owing to the flat dip of the vein, the cost would be heavy because of the number of levels from which it would be necessary to work. The Development company's production during April was 922 dry tons having a gross value of $33,907, or an average value per ton of $36.77. The ore came from all mines, from the operations of both the company and lessees.

The Grandma has started a cross-cut west from the north-east drift on the 815-ft. level. The drift was driven in a cross-vein without opening pay-ore, and a cross-cut will be extended to the foot-wall of the vein in what may be the last work on this level before sinking of the shaft is resumed. It is estimated that the wall will be reached within 100 ft. from the drift.

The Atlanta is driving south-east on the 1900-ft. level, in an 8-ft. shoot of unpayable ore in the main Atlanta vein. This shoot is regarded as the most promising opened by the main east cross-cut in penetrating the vein.

HOUGHTON, MICHIGAN

OPERATIONS AT THE CALUMET & HECLA.

Calumet & Hecla's tailing reclamation dredge is again in commission, after having been in drydock at Point Mills. The revolving screen has been removed. The grinding and leaching plants are at full capacity, and the oil-flotation plant connected therewith will be in operation in three months. The C. & H. output is down to a 50% basis. Thirteen stamps out of twenty-eight are dropping at the mills, crushing conglomerate ore only. A small quantity from the Osceola amygdaloid lode comes from necessary shipments of ore extracted during development. Fourteen furnaces are working at the smelter. The only construction work that C. & H. is doing is erection of steel for the flotation plant. When this plant is working all of the conglomerate slime will receive either treatment by flotation or leaching.

DIVIDE, NEVADA

CHAMBER OF COMMERCE FORMED.—LATEST DEVELOPMENTS.

Mine-owners and business-men of Divide and Tonopah have organized the Divide-Tonopah Chamber of Commerce. The following general council was elected: George Wingfield, H. C. Brougher, John H. Miller, George H. Garry, Thomas J. Lynch, E. J. Erickson, A. C.

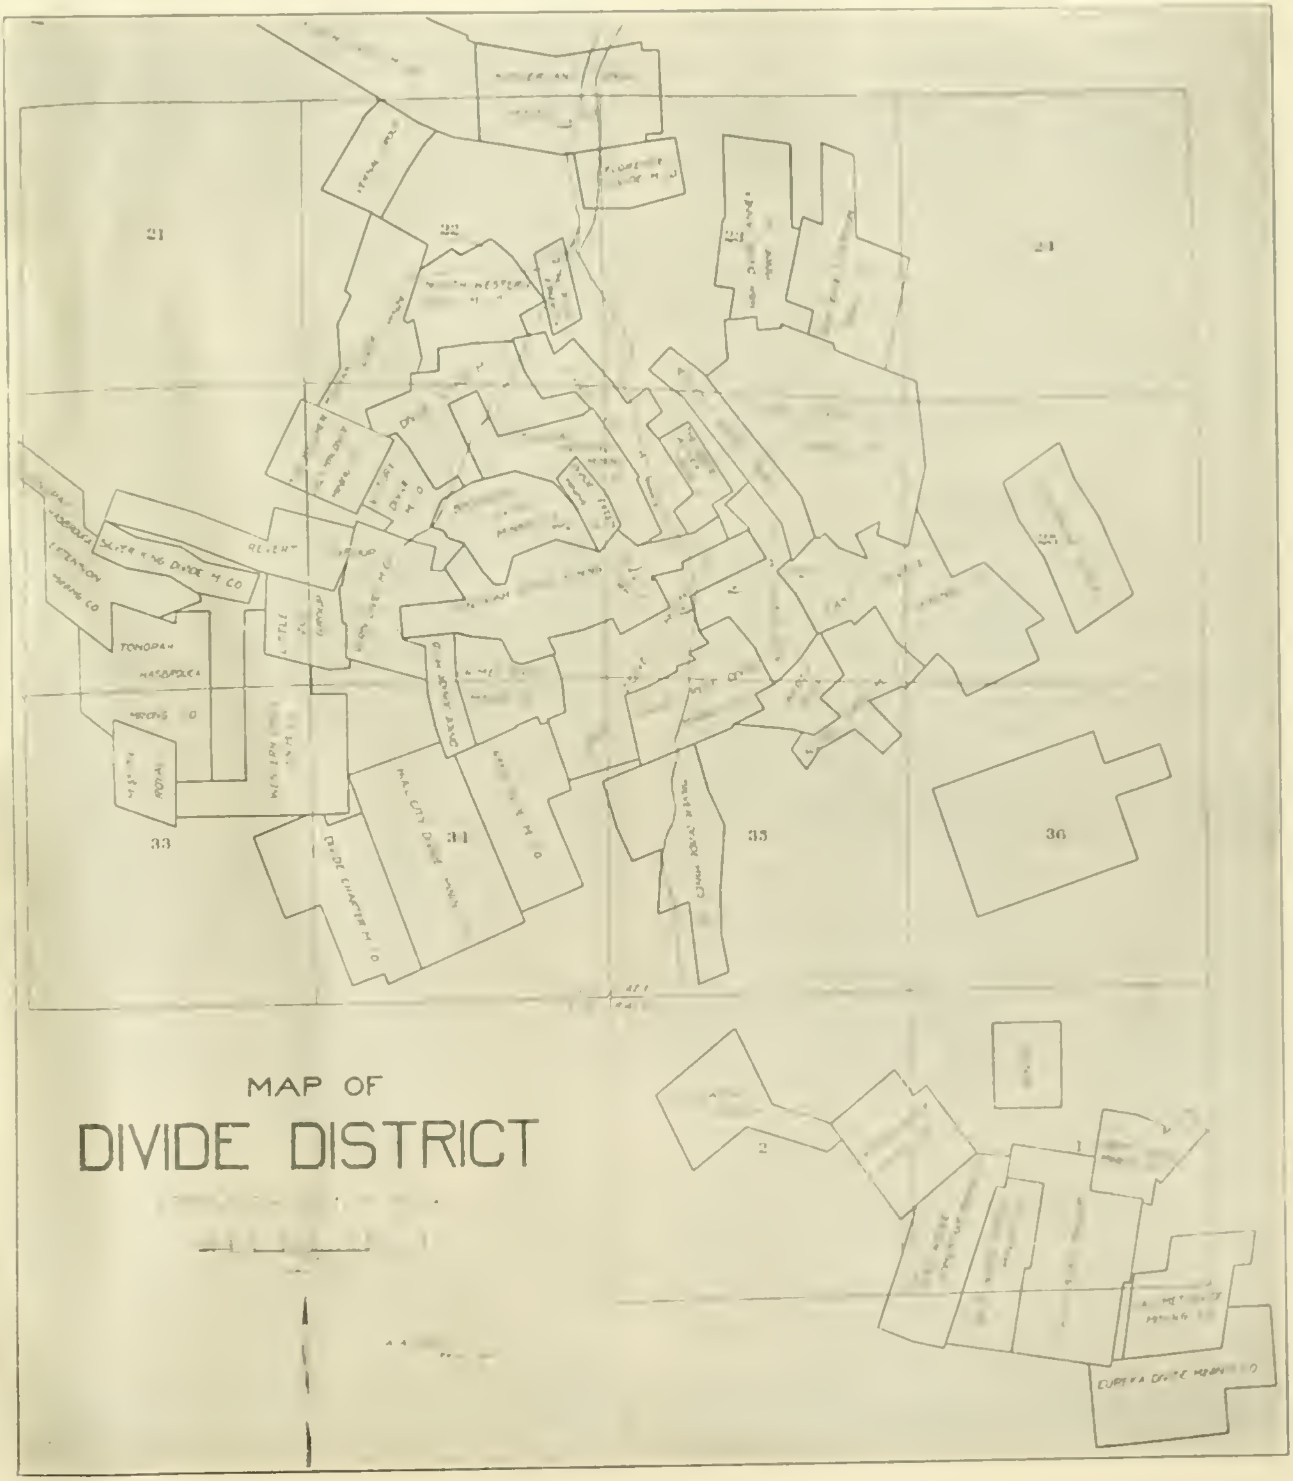
Raycraft, E. H. McMurray, J. Grant Crumley, M. M. Detch, James Grimes, J. M. Gilfoyle, Thomas Lindsay, Herman Albert, E. R. Kelly, J. K. Turner, John G. Kirchen, A. L. D'Arcy, Joseph H. Hutchinson, J. W. Hutchinson, and William Forman.

The Tonopah Divide company continues development, the main work being the cross-cut toward the vein at 585 ft. depth. Two raises have been driven from 480 to 370 ft., both in good ore. They were put up for ventilation and development purposes.

The Divide Extension, which opened rich ore at a depth of 45 ft. two weeks ago, in a new shaft sunk 450 ft. north of the old shaft, has proved the vein to be 55 ft. wide. A 6-in. streak on the hanging wall assays $1500 in silver and $100 in gold. Four feet next to this averages $90 per ton. The drift on the other side of the vein yields $100 across the face, and between the two drifts the ore averages $26. The old shaft is now 125 ft. deep. Machinery is being erected.

The Gold Reef Divide has a compressor and machine-drills, and sinking is under way below 135 ft. Present indications are reported to be favorable.

Among the many outside properties, prospecting for best sites for shafts is under way.



THE MINING SUMMARY

The War Minerals Relief Commission will be in San Francisco during July, the date not being fixed yet. According to an announcement made on the 23rd, claimants must file a brief upon the findings made by the Commission within 20 days. The claim will then be submitted to the Department of the Interior.

ALASKA

Fairbanks.—Boundaries of the Nenana recording precinct have been changed by order of court, giving that precinct more territory. The change is considered advantageous to miners, who will not be compelled to make the long journey to Fairbanks to record their papers.

Juneau.—All quartz mining companies in Alaska are complaining about the scarcity of labor. While all are working full time, more men are needed to obtain the desired results. The pay offered, from $4.50 to $6 per day, is sure, the accommodations are first class, and the work is steady, according to the May Monthly Bulletin of the Alaska Bureau of Publicity, of which E. J. White is chief. One trouble is that many of the men who went away during the War have not returned, and no others have come back to replace them.

CALIFORNIA

Bishop.—The Wilshire Consolidated Co. has added flotation equipment to its gold mine on Bishop creek and begun treatment of dumps. Unwatering of the mine has been started, and it is proposed to extract ore at capacity. With the improved mill the management hopes to treat the refractory ore without further trouble.

Darwin.—From its Lucky Jim mine, the Darwin Development Co. is shipping silver-lead ore to smelters in Utah. Operations were recently increased, and the property is being prepared for a larger output. Shipments of silver-lead ore are going out from the Rip Van Winkle, Wonder, Fernando, and other mines in this part. Numerous properties have been re-opened since silver passed the dollar mark.

Fresno.—Chrome miners in this county—about 40 in all—were to organize on June 28 to aid the War Minerals Relief Commission, which is to sit at Los Angeles and San Francisco early in July. Estimated losses in this region amount to $35,000. The chrome deposits are over 30 miles east and north-east of Fresno, near Piedra and Academy.

At the meeting of chrome men here last week it was decided to demand that the War Minerals Relief Commission hold a sitting at Fresno.

Grass Valley.—The cycle of events in the strike may be summarized as under:

Nine hundred men are out. At a meeting held on the 16th it was voted unanimously to strike for a wage increase of 50 cents. This decision was reached after a long discussion between the superintendents of the Empire, North Star, and Allison Ranch mines and the men. The managers were formally notified of the action on the 17th. During the conference, the following communication from the Empire Mines Co. was read: "We will be glad to welcome the return of our employees to their work. If we could raise the price of our product we would gladly increase wages. We sincerely hope that our employees will realize our position and return to their work." F. C. Nobs of the Empire, A. B. Foote of the North Star, and C. A. Brockington of the Golden Center each made a statement of considerable length. Mr. Foote said that the North Star had been run on a narrow margin for two years past, and continued operations because of a dislike to discharge men who had been with the company for many years. In his opinion it would have been a financial advantage to have closed the mine until the time was more favorable for gold mining. Mr. Brockington represented a promotion company, leasing, tributing, and contracting, in an effort to find ore. Increased wages would come from more assessments. Mr. Nobs stated that his mine was privately owned and he was not authorized to make a statement.

A former statement, and one of the points brought out in the controversy, that men from the Federal Employment Bureau at San Francisco were paid $4.50 per day at the North Star mine, was charged to a clerk's error, and Mr. Foote denied that his company placed an advertisement in the 'Chronicle' offering that rate.

Many surface men have signed the agreement, but there has been no enthusiasm to join. No attempt has been made by the engineers and pumpmen to leave their posts. The North Star men have not yet called for their checks. The Champion mine, near Nevada City, owned by the North Star, has not been affected; but if the men go out, pumps will be removed. A clean-up of the mill and cyanide plant was made on the 16th. At the Champion, a secret vote was taken on the 17th, but before voting, the superintendent, Roy Tremeroux, stated that they were either to close the property or keep it running. The vote resulted in 65 for operation and 9 against. Ten men quit but work was resumed.

The miners held another meeting on the 17th, at which the different committees appointed to interview the managers reported that the position remained as on the 13th. Mr. Ingram, State Senator, appealed to the men to consider the matter of inviting the State Labor Commissioner to come here and settle the trouble. Many favored the plan, but it was voted down by a large majority. The mine superintendents have not receded from the stand already taken. A motion was adopted to call out the pumpmen and enginemen on 48 hours' notice, and a committee was appointed to serve notice upon the superintendents on the 18th.

At the Pennsylvania and Empire mines, at Grass Valley, 19 underground mules were taken out.

On the 19th the pumps were being taken out of the North Star mine.

A conference was held on the 19th between a committee of citizens and miners, who later met the superintendents; but there was no result therefrom. The miners' organization on that night voted to extend the ultimatum given to withdraw the engine and pump-men in 24 hours. A committee of 12 citizens and 12 striking miners met in accordance with previous arrangement. A free discussion followed to devise some way out of the difficulty. There being no result, the same citizen committee invited the mine operators to confer, and a large part of the afternoon was spent in discussion. Nearly all the mines were represented;

nothing definite came of it. G. W. Starr, of the Empire, urged the men to return to work and help him carry out the plans under way at the mine to bring it to a condition whereby higher wages may be paid. The question of living costs came up, and he promised to assist in every way possible.

While the pumps are being removed from the North Star and Empire mines, both managements stated that this is but a precautionary measure, and did not necessarily mean an indefinite closing. Mr. Starr stated that the mines would be operated the moment the men returned.

On the 22nd, John S. Blair, deputy State Labor Commissioner, arrived at Grass Valley to investigate the dispute.

The engine and pumpmen at all mines quit work at 11 a.m. on Sunday.

C. A. Brockington of the Allison Ranch mine has stated that his company will accede to the new wage-schedule demanded by the miners for all men employed in those departments that have been affected by the strike, but only for a limited number so employed. At the same time he made it understood that only a few men would be affected, and that the remainder of the force was under the contract and tributing system, and in no way affected by the strike.

The miners decided that picketing should be enforced at once; this is to be confined to public streets and highways only. A peace committee was formed and members were to be on duty continuously to guard against possible violence or overt acts.

Porterville.—The new plant of the McKnight Fire Brick Co. commenced work on June 19. Chrome, magnesite, and silica from Californian deposits are used.

Trona.—In the Slate range of Inyo county, 8 miles northeast from this place, the Slate Range Minerals Co., whose head office is at Bakersfield, is operating. The number of men employed is from 20 to 40. Production in 1918 was 1,331,440 lb. of lead, 1786 oz. of gold, 64,389 oz. of silver, and 90,124 lb. of copper. The gross receipts were $142,822. The ore is mainly a lead carbonate with oxides, sulphates, and sulphides. The company is erecting a 50-ton concentrating mill, employing gravity and flotation. It has erected an 8-mile electric power-line. The mill is to treat low-grade ore, valued from $15 to $20 per ton. It is expected to be in operation by about July 15. There are three years supply blocked out. High-grade ore is shipped to the U. S. S. & R. Co. at Midvale, Utah. Morris B. Parker is superintendent.

Weaverville.—The contractor, F. Rolandi of San Francisco, for construction of 11 miles of highway in this county is preparing camps at Big Bar and North Fork, on the Trinity river. This road connects with and is part of the State highway from Eureka to Redding.

COLORADO

Bonanza.—The Rawley mine in Saguache county has been sold to Eastern people for a large sum. The main tunnel is 6235 ft. long, cutting orebodies at a depth of 1200 ft. Total workings amount to over 15,000 ft. Ore exposed is estimated at 200,000 tons, worth $25 per ton in silver, gold, copper, and lead. An aerial tram, 7 miles long, will connect with the proposed mill at Shirley on a branch of the D. & R. G. railroad.

Cripple Creek.—According to G. M. Taylor, the receiver, the Short Line will be in operation again by July 20. The roadbed is being repaired and a bridge re-built. One freight and one passenger train will be run for a start.

The United Gold Mines in May produced 1450 tons of ore worth $60,000. The Anderson & Benkelman lease at the Trail mine yielded 1250 tons of the total. Monthly royalties from lessees amount to $10,000. The company's cash balance is about $105,000.

A specimen from the 2100-ft. level of the Portland mine is on view at Colorado Springs. It assays [illegible]74 oz. of gold and [illegible]57 oz. of silver per ton. The ore was found on a waste pile on the tunnel-level. Water from the Portland flowing into the Roosevelt drainage tunnel is only [illegible]0 gallons per minute.

La Plata.—There is a marked contrast between the beginning of this season and that of last year, and the present outlook is favorable for heavy production. The principal incentive to mining here is the higher price of silver, although the ores are principally gold bearing with moderate silver content.

Red Mountain.—An important development is reported from the Barstow, being developed under lease by C. R. Wilfley & Co. A vein carrying numerous pockets of rich gold-silver ore has been found. The high grade ore is in narrow streaks.

IDAHO

Leadore.—The Sunset M. & M. Co. has started its new 100-ton mill. The ore carries 14% lead and 12 oz. silver per ton. The concentration ratio is 4 into 1. W. Van Wagenen is superintendent.

Murray.—The Yukon Gold Co.'s dredge on Prichard creek is being overhauled. The principal repair is to be an 18-ton spud, several steel plates being cracked. The hull is also to be riveted at the stern, while the revolving-screen and driving gear are receiving attention. The 6600-volt transformers are to be fireproofed.

Wallace.—The Idaho-Nevada Exploration Co.'s property near here was sold at forced sale on June 9 for $60,000. The mortgage and interest totaled $73,916. The original owners bid in for the mine.

The labor question in the Coeur d'Alene region is unchanged from last week, but it is believed that there will be no strike. R. M. McWade, U. S. Conciliation Commissioner from the Federal Department of Labor, arrived last week and is making a personal investigation from all concerned.

MICHIGAN

Houghton.—Copper production from this region during May was the lowest on record for any single month in 16 years, excepting the worst months of the strike period of 1913. The metal output was 13,106,220 lb., recovered from 555,550 tons of ore.

The Seneca has purchased the Gratiot property adjoining, for $25,000 cash and terms. The Lewisohn's arranged the deal. The Seneca is soon to start a cross-cut on its 1700-ft. level.

MONTANA

Anaconda.—The new 575-ft. stack at the Anaconda reduction works is in full working order, the second half of the furnaces being connected on June 9.

Basin.—This old district is to be revived by the financing of the Jib Mining Co. by Salt Lake and Montana people. A. E. Spriggs and Marcus Hewett are largely interested. The mines to be re-opened are the Hope and Katie, the former having been a large producer of silver ore, so has the latter. The district has produced many millions in silver. A new electric hoist is to be erected, and probably a mill.

NEVADA

Mason.—It is proposed to consolidate the Bluestone, Mason Valley, and Nevada Douglas properties in Lyon county. This will include the smelter at Thompson and the Nevada Copper Belt railway.

McGill.—Gold has been found in Rattlesnake canyon, and a small stampede set in last week.

Tonopah.—The West End and Jim Butler companies have made an agreement whereby the former is to lease a large block of the latter's ground directly south of the West End original claim. The West End will extract the ore and treat it, the profits to be its until the sum of $33,000 is reached, after which the profits will be divided between the two companies. This ground is part of that in dispute, and so settles the trouble.

The Tonopah Extension is driving a raise from the 1440-ft. level, and is in 10 ft. of milling ore, an important development.

Virginia City.—Both the Con. Virginia and Ophir mines are yielding rich ore, the former from 2100 ft., the latter from 1800 ft. depth. During the last three months they have produced $102,260 and $84,681, respectively.

UTAH

Bingham.—The Bingham Mines Co. pays 25 cents per share, equal to $37,500, on June 30. This is the second for 1919, and makes $637,500 to date.

Eureka.—The Chief Consolidated is busy putting in the new pumps at 1800, 1200, and 600 ft., where there are already small pumps at work. The new units have a capacity of 1000 g.p.m., compared with 260 for the present equipment.

Park City.—Miners on strike held a meeting on June 17 to decide whether they return to work or not. The resident class of men rather favored calling off the dispute, and in the end the strike was called off and the companies notified to that effect.

CANADA

British Columbia

Fernie.—A ludicrous situation has arisen from the strike here. S. Whitehouse, president of the local miner's union, has wired to the Hon. John Oliver, Premier of British Columbia, informing him that it was stated in a local paper that the Crow's Nest Pass Coal Co. intended to close its mine permanently. Mr. Whitehouse wanted to know what the Government would do, in the event of the company carrying out its threat, as such a course would mean the enforced idleness of a large number of men. Mr. Whitehouse is the president of the union that called the present strike. The Premier has replied, stating that he understands the company is taking such measures as it deems necessary under the circumstances to protect its property.

Grand Forks.—The Granby Consolidated smelter here was forced to suspend operations on the 21st on account of shortage of coke from Crows Nest Pass, where the coal mines are closed by a strike. The copper mines at Phoenix and the smelter here may be stopped for good.

Ontario

Kirkland Lake.—Preliminary work has been started on the new 7-mile motor road from Swastika to this place.

The Miner's Union has asked operators for a minimum of $1.50 per shift underground and $4 in the mills and on the surface, half time on Saturdays with full pay, time and a half for overtime and double time for Sundays, and recognition of the branch of the Union.

The strike that started is proving a 'boomerang', according to 'The Northern Miner' of Cobalt. Instead of getting demands, the Union has lost over half its members. About 300 men have left, and, despite the by-laws passed by the Union against leaving, 100 left by the morning train on the 15th. Ninety per cent of those leaving were foreigners, showing the high proportion of this class of labor employed and its instability. The situation is worrying Union officials, as the only ones remaining are a few single men living at the Union hall, and married men whom companies are allowing to stay in mine cottages. The strike threatens to smash the Union completely, as the exodus shows signs of continuing. Officials seem to have lost control of the men. All the mines are closed.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

John D. Kearns, of Vancouver, is here.

J. R. Finlay is at Bear Valley, California.

F. L. Sizer has returned from Tonopah, Nevada.

R. B. Lamb, of New York, is in Colorado on professional work.

Richard S. McIntyre has returned to Berkeley from Burma.

Leslie Webb, of the Wedge Mechanical Furnace Co. of Philadelphia, is here.

H. D. G. Reynolds is returning to the mines of the Irtysh Corporation in Siberia.

James F. Kemp has been re-appointed Professor of Geology in Columbia University.

Donald G. Campbell, of Seattle, has gone on a journey of exploration to Lost River, Alaska.

C. W. Adams has gone from the Murray plant to the East Helena plant of the A. S. & R. Co.

Karl Eilers, a vice-president of the A. S. & R. Co., was in San Francisco last week, on a tour of inspection.

Hallet R. Robbins, Captain in the Military Intelligence Division, has returned from Peking and is now at Washington.

Oliver E. Jager has been appointed metallurgist to the British-America Nickel Corporation at Nickelton, in Ontario, Canada.

H. K. Masters, of W. R. Grace & Co., has been elected a member of the Board of Managers of the New York Metal Exchange.

J. A. Burgess has been promoted from superintendent to general manager of the United Eastern Mining Co., at Oatman, Arizona.

Ben B. Lawrence, who recently underwent a serious operation, is sojourning in California, spending a few days at the Bohemian grove.

Forbes Rickard, of Denver, has been examining the old Cashin copper mine, in the Paradox district, Colorado, for the Michigan Securities Corporation.

Charles E. Newton has been appointed Dean of the Oregon School of Mines, Corvallis, Oregon. He was formerly Associate Professor of Metallurgy at that institution.

G. K. Williams, in charge of the mechanical engineering department of the Chile Exploration Co.'s property at Chuquicamata, Chile, was at Salt Lake City on June 14.

J. F. McClelland has resigned as professor at Yale University and is now connected with the Industrial Department of the Liberty National Bank of New York, at 120 Broadway.

V. H. Hughes, petroleum and mining geologist, announces that he has severed his connection with the firm of Valerius, McNutt & Hughes, and has opened offices at 326 Mayo Bdg., Tulsa, Oklahoma.

Scott Turner was married on June 25 to Miss Amy Prudden of Lansing, Michigan. He has succeeded **D'Arcy Weatherbe** as consulting engineer to the Mining Corporation of Canada, and will reside at Toronto.

Arthur C. Terrill, for the last four years head of the department of Mining Engineering at the University of Kansas, Lawrence, Kansas, has resigned and accepted an appointment with the Kansas State Geological Survey. On July 1 he will move to Baxter Springs to take charge of lead and zinc investigations in south-eastern Kansas.

John J. Broderick, of the Broderick & Bascom Rope Co., died on June 7 at St. Louis.

THE METAL MARKET

METAL PRICES

San Francisco, June 24

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8.50
Copper, electrolytic, cents per pound	18.25
Lead, pig, cents per pound	5.65—6.85
Platinum, pure, per ounce	$105
Platinum, 10% iridium, per ounce	$115
Quicksilver, per flask of 75 lb	$95
Spelter, cents per pound	8.25
Zinc-dust, cents per pound	9—12

EASTERN METAL MARKET

(By wire from New York)

June 24.—Copper is strong and advancing. Lead is active and firm. Spelter is active and higher.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918, and will continue to pay $1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

The Director of the Mint, Raymond T. Baker, is reported to have said at Reno on June 20 that the price of silver will not fall below one dollar per ounce in less than seven years, and probably not for several years later than that time. He said that the probability of Congress repealing the Pittman silver bill was remote, and continued: "If the Government were to purchase the entire silver production of the United States for the next five years, the silver to be melted and sold to the allies under the terms of the Pittman bill would not be replaced. It would be impossible to purchase the entire output of the mines of the United States, hence it will be a somewhat longer period than five years, I should say not less than seven years, before the replacement would be completed. The Government has melted under the Pittman bill, 270,000,000 oz., and 200,000,000 oz. has been sent abroad."

Zinc ore, basis 60% metal, averaged $41 per ton at Joplin last week. The Tri-State output was 8794 tons. Prices gained $1, due to better demand.

Spelter produced in the United States during 1918, according to C. E. Siebenthal of the U. S. Geological Survey, totaled 492,405 short tons from domestic sources, compared with 584,597 tons in 1917. Metal from foreign ore decreased from 84,976 to 25,522 tons, and redistilled secondary from 16,835 to 9597 tons. The grades and prices were:

Grade	1917 Tons	1917 Cents	1918 Tons	1918 Cents
A	97,707	14.0	129,023	11.1
B	69,189	12.7	68,087	10.7
C	148,749	9.4	98,584	8.0
D	370,763	9.0	230,930	7.9
Total and average	686,408	10.2	527,524	9.1
Total value	$140,027,000		$96,009,000	

Before the Ways and Means Committee of the House of Representatives at Washington last week, Paul Edwards, representing Joplin zinc operators, asked for a duty of 2% on metal content of imported zinc ore instead of the existing duty of 10% ad valorem. He explained it cost $60 per ton to get American zinc ore to smelters, while it cost only $24 per ton to get foreign zinc ore to smelters. Chairman Fordney suggested that tariff valuation on imported ores be made on American basis, instead of foreign basis of price.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c., f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

The War Trade Board announces that applications will now be considered for licenses to import pig tin and all metal alloys containing tin, including tin drosses, tin oxides, solder drosses, type metals, anti-friction metals, waste metals, and other metals containing tin; subject, however, to the following conditions and limitations: (1) that such licenses will permit the importation only of shipments made from points of origin on or after June 30, 1919; and (2) that such import licenses will not be valid for entry until August 1, 1919.

Eastern Metal Market

New York, June 18.

The markets are all moderately active and prices are generally steady to firm, with a slight easing in some cases.

Copper demand is reported to have revived again, and prices are advancing.

Lead has advanced, but is again quiet after a short buying movement.

Tin is very quiet, but prospects appear to be better for an open market.

Zinc rose suddenly last week with a sharp advance, but prices and demand have eased off again to some extent.

COPPER

The market today reached the 18c. level for electrolytic, and the tone is strong and firm. Demand has again appeared in increased volume this week, after three or four days of relative quietness. The movement a week ago resulted in an advance for electrolytic to 17.50 to 17.75c., New York, at which level the market turned quiet. The cause of the movement a week ago is now rather freely acknowledged as due, in part at least, to buying by Japanese consumers. The present advance proceeds largely from domestic consumers. Lake copper is quoted today at 18.12½ to 18.25c., New York. There is also some export demand, but as yet it is not heavy when compared with normal times. For August delivery many producers are well sold, some to a larger extent than desired and for far future shipment they are generally reluctant to commit themselves, although demand is fair.

Japan's buying is said to have been put through because it is cheaper for them to buy in America than it is to produce in their own country. It is no longer profitable for them to work some of their old mines, and others were gouged in taking advantage of the high war prices to such an extent that they are now out of business. Japan is now branching out for a share of the world's trade in manufactured copper and brass, and can be counted on as a regular buyer of American copper, having increased facilities for manufacturing during the War.

IRON AND STEEL

Assertions as to the improvement in steel are in stronger terms this week. In a number of finished lines, orders are larger, and some assert that the May output will be the lowest for the year. Steel-mill operations of one large interest in the Pittsburgh district have advanced to a 75% rate. One or two blast-furnaces may be blown-in there; blowing-out of furnaces has been the rule lately. The leading producer has been booking sheets for export at the rate of 1000 tons per day, with wire products an important item in the export demand Italy has bought 1000 tons of heavy rails. Ocean-freight rates have been reduced, making British markets more accessible to American steel. The special heralded drive for the organization of steel works labor is not a new departure. For many months, with the help of the War Labor Board, the campaign to unionize the industry has gone on. The pig-iron market is still active, but buying is less spirited than two weeks ago

LEAD

The market has again become quiet after a fair amount of purchasing during the past week On June 11, the American Smelting & Refining Co. advanced its price from 5.25c. to 5.40c., New York, which resulted in a considerable amount of business; but after this, demand slowed down. The outside market immediately came abreast that of the leading interest. At present, some outside lots are available at slightly under the Trust price, and we quote the market at 5.35c., New York, or 5.10c., St. Louis, with the tone steady.

TIN

An open tin market is surely nearer. So far as the confines of the United States are concerned there may be open trading in the metal in less than two weeks. George Armsby, on June 16, announced that on that date only 577 tons of the allocated metal remains unsold, and that all restrictions in the United States will be removed as soon as the remainder is disposed of, with a definite announcement of the removal of restrictions promised in due course. Of equal interest and importance is the announcement of the War Trade Board that licenses will be permitted for the importation of tin and tin ore shipments from points of origin on and after June 30, and that such licenses will not be valid for entry until August 1. One interpretation of these interesting news items is to the effect that they mean that shipments from the Straits and from England can be made in July, valid for entry into the United States, however, only after August 1. A free and open world market is looked for early in August at the latest, and some interesting developments are likely even in July, when a free market is probable within the United States. At present the market is quiet. During the last week there have been sales of July shipment from the East at 52.25c., but the interest is not active in this position. Buying for shipment, when restrictions are removed, has been spasmodic over the last two months, but the volume has been fairly large amounting to 4000 to 5000 tons, it is estimated. The onl tin available continues to be quoted at 72.50c., New Yor the fixed price.

ZINC

About the middle of last week the zinc market took a sudden spurt, and rose to higher levels as a result of increased demand. The revival of interest came both from dealers and from export buyers. So insistent was the buying that prices for prime Western rose to 6.62½c., St. Louis, or 6.97½c., New York, on Wednesday, at which levels there was a good turnover. One producer reports sales at 6.5c., St. Louis. Since then demand has subsided and values have fallen slightly until today quotations for prime Wester for early delivery are 6.50c., St. Louis, or 6.85c., New York. There is some export inquiry reported with sales made to Japan and other countries.

ORES

Manganese: Indian ore is firmer at 70c. per uni seaboard. Demand is light and supplies plentiful.

Manganese-Iron Alloys: There are inquiries fo 1000 tons of ferro before the market. Prices are firm a $125, delivered, for the American alloy, and $121, seaboard, for the British. Most re-sale material has disappeared, and what is left is higher at a minimum of $115 [illegible] $120. Spiegel is quiet at $27 to $30, furnace, with sales aggregating 500 tons last week, most of it at $30, furnace.

Molybdenum: Buying is hand-to-mouth, with quotations nominal at 65 to 75c. per pound of MoS_2 in regul concentrates.

Tungsten: Some business has been done in th last two weeks, but less this last week than a week ago. ue statement is to the effect that the ore available at $ per unit has been absorbed, while $10 is asked for otr grades, such as high-grade and Bolivian ore. Some Calrnian ore is quoted as high as $17, delivered, Eastern ints. No test of the ferro-tungsten market has been.reped, but it is believed that values are around $1 per pound contained tungsten.
